Guidelines for OpenVMS Cluster Configurations

Order Number: AA–Q28LE–TK

April 2001

OpenVMS Cluster availability, scalability, and system management benefits are highly dependent on configurations, applications, and operating environments. This guide provides suggestions and guidelines to help you maximize these benefits.

Revision/Update Information: This manual supersedes Guidelines for OpenVMS Cluster Configurations Version 7.2-1.

Software Version: OpenVMS Alpha Version 7.3
OpenVMS VAX Version 7.3

Compaq Computer Corporation
Houston, Texas
Contents

Preface ............................................................ xix

1 Overview of OpenVMS Cluster System Configuration
   1.1 Mixed Alpha and VAX Clusters ................................ 1–1
   1.2 Hardware Components ........................................ 1–2
   1.3 Software Components ........................................ 1–3
      1.3.1 OpenVMS Operating System Components .............. 1–3
      1.3.2 Networking Components ................................ 1–5
      1.3.3 Storage Enhancement Software ....................... 1–6
      1.3.4 System Management Software ....................... 1–6
      1.3.5 Business Applications ........................... 1–7
   1.4 Configuring an OpenVMS Cluster System .................... 1–7
      1.4.1 General Configuration Rules ....................... 1–7

2 Determining Business and Application Requirements
   2.1 Determining Business Requirements ....................... 2–1
      2.1.1 Budget ........................................ 2–1
      2.1.2 Availability .................................... 2–2
      2.1.3 Scalability and Future Growth ..................... 2–2
      2.1.4 Physical Location Requirements .................... 2–2
      2.1.5 Security ....................................... 2–3
   2.2 Determining Application Requirements .................... 2–3
      2.2.1 Adding Memory .................................. 2–3
      2.2.2 Balancing Processor, Memory, and I/O Resources .... 2–4
      2.2.3 Tools and Utilities ................................ 2–4
      2.2.4 System Management Tools from OpenVMS Partners ... 2–5
      2.2.5 Other Configuration Aids ........................ 2–6

3 Choosing OpenVMS Cluster Systems
   3.1 Alpha and VAX Architectures ............................. 3–1
   3.2 Types of Systems ....................................... 3–1
   3.3 Choosing Systems ....................................... 3–1
   3.4 Scalability Considerations ............................... 3–2
   3.5 Availability Considerations ............................. 3–3
   3.6 Performance Considerations ............................ 3–3
   3.7 System Specifications .................................. 3–3
4 Choosing OpenVMS Cluster Interconnects

4.1 Characteristics ............................................ 4–1
4.2 Comparison of Interconnect Types ............................................ 4–2
4.3 Multiple Interconnects ........................................ 4–3
4.4 Mixed Interconnects ........................................ 4–3
4.5 Interconnects Supported by Alpha and VAX Systems ................ 4–4
4.6 Fibre Channel Interconnect .................................... 4–5
4.6.1 Advantages ............................................ 4–5
4.6.2 Throughput ............................................ 4–5
4.6.3 Supported Adapter ........................................ 4–6
4.7 MEMORY CHANNEL Interconnect .................................... 4–6
4.7.1 Advantages ............................................ 4–6
4.7.2 Throughput ............................................ 4–7
4.7.3 Supported Adapter ........................................ 4–7
4.8 SCSI Interconnect ........................................ 4–7
4.8.1 Advantages ............................................ 4–8
4.8.2 Throughput ............................................ 4–8
4.8.3 SCSI Interconnect Distances ................................ 4–8
4.8.4 Supported Adapters, Bus Types, and Computers ............... 4–9
4.9 CI Interconnect ............................................ 4–10
4.9.1 Advantages ............................................ 4–10
4.9.2 Throughput ............................................ 4–10
4.9.3 Supported Adapters and Bus Types ............................ 4–11
4.9.4 Multiple CI Adapters .................................... 4–11
4.9.5 Configuration Guidelines for CI Clusters ....................... 4–11
4.10 Digital Storage Systems Interconnect (DSSI) ....................... 4–11
4.10.1 Advantages ............................................ 4–12
4.10.2 Maintenance Consideration ..................................... 4–12
4.10.3 Throughput ............................................ 4–12
4.10.4 DSSI Adapter Types ...................................... 4–12
4.10.5 Supported Adapters and Bus Types ............................ 4–12
4.10.6 DSSI-Connected Storage .................................... 4–13
4.10.7 Multiple DSSI Adapters .................................... 4–13
4.10.8 Configuration Guidelines for DSSI Clusters ..................... 4–13
4.11 LAN Interconnects ........................................... 4–14
4.11.1 Multiple LAN Adapters ...................................... 4–14
4.11.1.1 Multiple LAN Path Load Distribution .................. 4–14
4.11.1.2 Increased LAN Path Availability ....................... 4–15
4.11.2 Configuration Guidelines for LAN-Based Clusters ............. 4–15
4.11.3 Ethernet (10/100) and Gigabit Ethernet Advantages ........... 4–15
4.11.4 Ethernet (10/100) and Gigabit Ethernet Throughput ........... 4–15
4.11.5 Ethernet Adapters and Buses ................................ 4–16
4.11.6 Ethernet-to-FDDI Bridges and Switches ....................... 4–17
4.11.7 Configuration Guidelines for Gigabit Ethernet Clusters ......... 4–17
4.11.8 ATM Advantages ........................................ 4–17
4.11.9 ATM Throughput ........................................ 4–18
4.11.10 ATM Adapters ......................................... 4–18
4.12 Fiber Distributed Data Interface (FDDI) ......................... 4–18
4.12.1 FDDI Advantages ........................................ 4–18
4.12.2 FDDI Node Types ...................................... 4–18
4.12.3 FDDI Distance .......................................... 4–18
4.12.4 FDDI Throughput ........................................ 4–19
4.12.5 FDDI Adapters and Bus Types ............................... 4–19
4.12.6 Storage Servers for FDDI-Based Clusters ..................... 4–19
5 Choosing OpenVMS Cluster Storage Subsystems

5.1 Understanding Storage Product Choices .................................. 5–1
  5.1.1 Criteria for Choosing Devices ...................................... 5–2
  5.1.2 How Interconnects Affect Storage Choices ............................ 5–2
  5.1.3 How Floor Space Affects Storage Choices ............................. 5–3
5.2 Determining Storage Capacity Requirements .......................... 5–3
  5.2.1 Estimating Disk Capacity Requirements .............................. 5–3
  5.2.2 Additional Disk Capacity Requirements ............................... 5–4
5.3 Choosing Disk Performance Optimizers ................................. 5–4
  5.3.1 Performance Optimizers ........................................... 5–4
5.4 Determining Disk Availability Requirements .......................... 5–6
  5.4.1 Availability Requirements ......................................... 5–6
  5.4.2 Device and Data Availability Optimizers ............................ 5–6
5.5 CI Based Storage .......................................................... 5–7
  5.5.1 Supported Controllers and Devices .................................. 5–7
5.6 DSSI Storage ........................................................................ 5–7
  5.6.1 Supported Devices ..................................................... 5–7
5.7 SCSI-Based Storage .......................................................... 5–8
  5.7.1 Supported Devices ..................................................... 5–8
5.8 Fibre Channel Based Storage .................................................. 5–8
  5.8.1 Storage Devices ....................................................... 5–8
5.9 Host-Based Storage ............................................................ 5–8
  5.9.1 Internal Buses ............................................................ 5–8
  5.9.2 Local Adapters ........................................................... 5–9

6 Configuring Multiple Paths to SCSI and Fibre Channel Storage

6.1 Overview of Multipath SCSI Support ..................................... 6–2
  6.1.1 Direct SCSI to Direct SCSI Failover .................................. 6–2
  6.1.2 Direct SCSI to MSCP Served Failover ................................. 6–4
  6.1.3 Configurations Combining Both Types of Multipath Failover ..... 6–5
6.2 Configuration Requirements and Restrictions .......................... 6–6
6.3 HSx Failover Modes ............................................................ 6–7
  6.3.1 Transparent Failover Mode ............................................ 6–7
  6.3.2 Multibus Failover Mode ............................................... 6–9
  6.3.3 Port Addressing for Controllers in Multibus Mode ............... 6–10
6.4 Parallel SCSI Multipath Configurations ................................. 6–11
  6.4.1 Transparent Failover .................................................... 6–11
  6.4.2 Multibus Failover and Multiple Paths ................................ 6–12
  6.4.3 Configurations Using Multiported Storage Controllers ........... 6–13
6.5 Device Naming for Parallel SCSI Multipath Configurations ........... 6–15
  6.5.1 Review of Node Allocation Classes ................................... 6–16
  6.5.2 Review of Port Allocation Classes .................................... 6–16
  6.5.3 Device Naming Using HSZ Allocation Classes ....................... 6–17
6.6 Fibre Channel Multipath Configurations ................................ 6–19
6.7 Implementing Multipath Configurations .................................. 6–21
  6.7.1 Valid Multipath Configurations ....................................... 6–22
  6.7.2 Invalid Multipath Configuration ...................................... 6–23
  6.7.3 Multipath System Parameters ........................................ 6–24
  6.7.4 Path Identifiers ......................................................... 6–25
  6.7.5 Displaying Paths ....................................................... 6–26
    6.7.5.1 Displaying Paths With SHOW DEVICE/FULL .................. 6–26
    6.7.5.2 Displaying Paths With SHOW DEVICE/MULTIPATH_SET .... 6–28
  6.7.6 Path Polling .............................................................. 6–28
7 Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.1 Overview of Fibre Channel ............................................. 7–2
7.2 Fibre Channel Configuration Support .................................. 7–4
7.2.1 Fibre Channel Remedial Kits .......................................... 7–7
7.2.2 Mixed-Version and Mixed-Architecture Cluster Support ........... 7–7
7.2.3 Fibre Channel and Volume Shadowing for OpenVMS .............. 7–8
7.2.4 Fibre Channel and OpenVMS Galaxy Configurations .............. 7–8
7.3 Example Configurations .................................................. 7–8
7.3.1 Single Host with Dual-Ported Storage .................................. 7–8
7.3.2 Multiple Hosts With One Dual-Ported Storage Controller ........ 7–9
7.3.3 Multiple Hosts With Storage Controller Redundancy .............. 7–10
7.3.4 Multiple Hosts With Multiple Independent Switches ............. 7–11
7.3.5 Multiple Hosts With Dual Fabrics ..................................... 7–12
7.3.6 Multiple Hosts With Larger Fabrics .................................. 7–13
7.4 Fibre Channel Addresses, WWIDs, and Device Names .................. 7–14
7.4.1 Fibre Channel Addresses and WWIDs .................................. 7–14
7.4.2 OpenVMS Names for Fibre Channel Devices ......................... 7–16
7.4.2.1 Fibre Channel Storage Adapter Names ................................ 7–16
7.4.2.2 Fibre Channel Path Names ............................................ 7–17
7.4.2.3 Fibre Channel Disk Device Identification ......................... 7–17
7.5 Fibre Channel Tape Support (Alpha) ..................................... 7–19
7.5.1 Minimum Hardware Configuration .................................... 7–19
7.5.2 Overview of Fibre Channel Tape Device Naming ..................... 7–19
7.5.2.1 Tape and Medium Changer Device Names .......................... 7–20
7.5.2.2 Use of Worldwide Identifiers (WWIDs) ............................... 7–20
7.5.2.3 File-Based Device Naming ............................................ 7–21
7.5.3 New Commands and Features for Fibre Channel Tape Devices .... 7–23
7.5.4 Configuring a Fibre Channel Tape Device ............................. 7–23
7.5.4.1 Basic Configuration Steps: Summary ............................... 7–23
7.5.4.2 Basic Configuration Steps: Details .................................. 7–24
7.5.5 Changing the Name of an Existing Fibre Channel Tape Device .... 7–26
7.5.6 Moving a Physical Tape Device on Fibre Channel .................. 7–27
7.5.7 Serving a Fibre Channel Tape Device .................................. 7–27
7.5.8 Replacing a Fibre Channel Tape Device ............................... 7–27
7.5.9 Determining the Physical Location of a Fibre Channel Tape Device .................................................. 7–28
7.5.10 Accessing a Fibre Channel Tape Device in a Standalone Environment .................................................. 7–28
7.5.11 Using an MDR with Dual Fibre Ports .................................. 7–28
7.6 Using the AlphaServer Console for Configuring FC ...................... 7–29
7.6.1 Viewing the FC Configuration from the Console ..................... 7–29
7.6.2 Setting Up FC Disks for Booting and Dumping ....................... 7–32
7.7 Setting Up an HSG for Use with OpenVMS ............................... 7–35
7.7.1 Setting a Dual HSG to Multibus Failover Mode ....................... 7–36
7.7.2 Setting an HSG to SCSI-3 Mode ........................................ 7–38
7.7.3 Setting the Device Identifier for the CCL ............................. 7–39
9 Configuring CI OpenVMS Clusters for Availability and Performance

9.1 CI Components .................................................. 9–1
9.2 Configuration Assumptions .................................... 9–2
9.3 Configuration 1 .................................................. 9–2
  9.3.1 Components ................................................ 9–3
  9.3.2 Advantages ................................................. 9–3
  9.3.3 Disadvantages .............................................. 9–4
  9.3.4 Key Availability and Performance Strategies .......... 9–4
9.4 Configuration 2 .................................................. 9–4
  9.4.1 Components ................................................ 9–5
  9.4.2 Advantages ................................................. 9–6
  9.4.3 Disadvantages .............................................. 9–7
  9.4.4 Key Availability and Performance Strategies .......... 9–7
9.5 Configuration 3 .................................................. 9–7
  9.5.1 Components ................................................ 9–9
  9.5.2 Advantages ................................................. 9–10
  9.5.3 Disadvantages .............................................. 9–10
  9.5.4 Key Availability and Performance Strategies .......... 9–10
9.6 Configuration 4 .................................................. 9–10
  9.6.1 Components ................................................ 9–12
  9.6.2 Advantages ................................................. 9–13
  9.6.3 Disadvantages .............................................. 9–13
  9.6.4 Key Availability and Performance Strategies .......... 9–13
9.7 Summary ...................................................... 9–13

10 Configuring OpenVMS Clusters for Scalability

10.1 What Is Scalability? ........................................... 10–1
  10.1.1 Scalable Dimensions ...................................... 10–1
10.2 Strategies for Configuring a Highly Scalable OpenVMS Cluster 10–3
  10.2.1 Scalability Strategies .................................... 10–3
10.3 Scalability in CI OpenVMS Clusters .......................... 10–4
  10.3.1 Two-Node CI OpenVMS Cluster .......................... 10–4
  10.3.2 Three-Node CI OpenVMS Cluster ......................... 10–5
  10.3.3 Seven-Node CI OpenVMS Cluster ......................... 10–7
  10.3.4 Guidelines for CI OpenVMS Clusters .................... 10–8
  10.3.5 Guidelines for Volume Shadowing in CI OpenVMS Clusters 10–8
10.4 Scalability in DSSI OpenVMS Clusters ....................... 10–11
  10.4.1 Two-Node DSSI OpenVMS Cluster ....................... 10–11
  10.4.2 Four-Node DSSI OpenVMS Cluster with Shared Access 10–12
  10.4.3 Four-Node DSSI OpenVMS Cluster with Some Nonshared Access 10–13
10.5 Scalability in MEMORY CHANNEL OpenVMS Clusters ........ 10–15
  10.5.1 Two-Node MEMORY CHANNEL Cluster ................... 10–15
  10.5.2 Three-Node MEMORY CHANNEL Cluster .................. 10–16
  10.5.3 Four-Node MEMORY CHANNEL OpenVMS Cluster ......... 10–17
10.6 Scalability in SCSI OpenVMS Clusters ....................... 10–18
  10.6.1 Two-Node Fast-Wide SCSI Cluster ...................... 10–18
  10.6.2 Two-Node Fast-Wide SCSI Cluster with HSZ Storage 10–19
  10.6.3 Three-Node Fast-Wide SCSI Cluster .................... 10–20
  10.6.4 Four-Node Ultra SCSI Hub Configuration ............... 10–22
10.7 Scalability in OpenVMS Clusters with Satellites ............ 10–23
  10.7.1 Six-Satellite OpenVMS Cluster .......................... 10–23
  10.7.2 Six-Satellite OpenVMS Cluster with Two Boot Nodes .... 10–24
  10.7.3 Twelve-Satellite LAN OpenVMS Cluster with Two LAN Segments 10–25
10.7.4  Forty-Five Satellite OpenVMS Cluster with FDDI Ring  ..........  10–26
10.7.5  High-Powered Workstation OpenVMS Cluster ...................  10–27
10.7.6  Guidelines for OpenVMS Clusters with Satellites ............  10–29
10.7.7  Extended LAN Configuration Guidelines .....................  10–29
10.7.8  System Parameters for OpenVMS Clusters .....................  10–31
10.8  Scaling for I/Os ............................................  10–31
10.8.1  MSCP Served Access to Storage ..............................  10–32
10.8.2  Disk Technologies ........................................  10–33
10.8.3  Read/Write Ratio ........................................  10–33
10.8.4  I/O Size ................................................  10–33
10.8.5  Caches ................................................  10–34
10.8.6  Managing “Hot” Files .....................................  10–34
10.8.7  Volume Shadowing ........................................  10–35

11  OpenVMS Cluster System Management Strategies

11.1  Simple and Complex Configurations ...............................  11–1
11.2  System Disk Strategies ........................................  11–2
11.2.1  Single System Disk .......................................  11–2
11.2.2  Multiple System Disks ......................................  11–4
11.2.3  Multiple System-Disk OpenVMS Cluster .......................  11–5
11.2.4  Dividing an OpenVMS Cluster System .........................  11–6
11.2.5  Summary: Single Versus Multiple System Disks ..............  11–7
11.3  OpenVMS Cluster Environment Strategies .......................  11–8
11.3.1  Common Environment .......................................  11–8
11.3.2  Putting Environment Files on a Separate, Common Disk ....  11–9
11.3.3  Multiple Environments ......................................  11–9
11.4  Additional Multiple-Environment Strategies .....................  11–10
11.4.1  Using Multiple SYSUAF.DAT Files ..........................  11–10
11.4.2  Using Multiple Queue Managers .............................  11–11
11.5  Quorum Strategies ............................................  11–11
11.5.1  Quorum Strategy Options ...................................  11–11
11.6  State Transition Strategies .....................................  11–12
11.6.1  Dealing with State Transitions ................................ 11–12
11.7  Migration and Warranted Support for Multiple Versions ........  11–13
11.8  Alpha and VAX Systems in the Same OpenVMS Cluster ...........  11–14
11.8.1  OpenVMS Cluster Satellite Booting Across Architectures ...  11–14
11.8.2  Restrictions .............................................  11–15
11.9  Determining Backup and Storage Management Strategies .......  11–15
11.9.1  Steps for Determining a Backup Strategy ....................  11–15
11.10  Disk Backup ................................................  11–15
11.11  Tape Backup ................................................  11–16
11.11.1  For More Information ....................................  11–16
11.11.2  Benefits of Unattended Backup ............................  11–16
11.11.3  Archive/Backup System for OpenVMS .......................  11–17
11.11.4  StorageTek 4400 ACS ....................................  11–17
11.11.5  Tape-Drive Performance and Capacity .......................  11–17
## A SCSI as an OpenVMS Cluster Interconnect

D Multiple-Site OpenVMS Clusters

D.1 What is a Multiple-Site OpenVMS Cluster System? ........................................ D–1
D.1.1 ATM, DS3, and FDDI Intersite Links .................................................. D–2
D.1.2 Benefits of Multiple-Site OpenVMS Cluster Systems .......................... D–2
D.1.3 General Configuration Guidelines .................................................. D–4
D.2 Using FDDI to Configure Multiple-Site OpenVMS Cluster Systems ........ D–4
D.3 Using WAN Services to Configure Multiple-Site OpenVMS Cluster Systems .................................................. D–5
D.3.1 The ATM Communications Service ........................................ D–5
D.3.2 The DS3 Communications Service (T3 Communications Service) .... D–6
D.3.3 FDDI-to-WAN Bridges ........................................................................ D–6
D.3.4 Guidelines for Configuring ATM and DS3 in an OpenVMS Cluster System ......................................................................... D–7
D.3.4.1 Requirements .................................................................................. D–7
D.3.4.2 Recommendations ........................................................................ D–8
D.3.5 Availability Considerations .............................................................. D–10
D.3.6 Specifications ..................................................................................... D–10

This document can help you design an OpenVMS Cluster configuration to suit your business, application, and computing needs. It provides information to help you choose systems, interconnects, storage devices, and software. It can also help you combine these components to achieve high availability, scalability, performance, and ease of system management.

**Intended Audience**

This document is for people who purchase or recommend the purchase of OpenVMS Cluster products and for people who configure OpenVMS Cluster systems. It assumes a basic understanding of computers and OpenVMS Cluster concepts.

**About This Guide**

OpenVMS Cluster systems are designed to act as a single virtual system, even though they are made up of many components and features, as shown in Figure 1.

**Figure 1  OpenVMS Cluster System Components and Features**
Understanding the components and features of an OpenVMS Cluster configuration can help you to get the most out of your cluster. Table 1 shows how this guide is organized to explain these cluster concepts.

Conventions

VMScluster systems are now referred to as OpenVMS Cluster systems. Unless otherwise specified, references to OpenVMS Clusters or clusters in this document are synonymous with VMSclusters.

In this manual, every use of DECwindows and DECwindows Motif refers to DECwindows Motif for OpenVMS software.

The following conventions are also used in this manual:

Ctrl/x A sequence such as Ctrl/x indicates that you must hold down the key labeled Ctrl while you press another key or a pointing device button.

PF1 x A sequence such as PF1 x indicates that you must first press and release the key labeled PF1 and then press and release another key or a pointing device button.

Return In examples, a key name enclosed in a box indicates that you press a key on the keyboard. (In text, a key name is not enclosed in a box.)

In the HTML version of this document, this convention appears as brackets, rather than a box.
A horizontal ellipsis in examples indicates one of the following possibilities:

- Additional optional arguments in a statement have been omitted.
- The preceding item or items can be repeated one or more times.
- Additional parameters, values, or other information can be entered.

A vertical ellipsis indicates the omission of items from a code example or command format; the items are omitted because they are not important to the topic being discussed.

() In command format descriptions, parentheses indicate that you must enclose the options in parentheses if you choose more than one.

[] In command format descriptions, brackets indicate optional elements. You can choose one or more options, or no options. (Note, however, that brackets are not optional in the syntax of a directory name in an OpenVMS file specification or in the syntax of a substring specification in an assignment statement.)

[] In command format descriptions, vertical bars separating items inside brackets indicate that you choose one, none, or more than one of the options.

{} In command format descriptions, braces indicate a required choice of options; you must choose one of the options listed.

**bold text** This text style represents the introduction of a new term or the name of an argument, an attribute, or a reason.

*italic text* Italic text indicates important information, complete titles of manuals, or variables. Variables include information that varies in system output (Internal error number), in command lines (/PRODUCER=name), and in command parameters in text (where dd represents the predefined code for the device type).

**UPPERCASE TEXT** Uppercase text indicates a command, the name of a routine, the name of a file, or the abbreviation for a system privilege.

**Monospace text** Monospace type indicates code examples and interactive screen displays.

- A hyphen at the end of a command format description, command line, or code line indicates that the command or statement continues on the following line.

numbers All numbers in text are assumed to be decimal unless otherwise noted. Nondecimal radices—binary, octal, or hexadecimal—are explicitly indicated.
Overview of OpenVMS Cluster System Configuration

This chapter contains information about OpenVMS Cluster hardware and software components, as well as general configuration rules.

1.1 Mixed Alpha and VAX Clusters

An OpenVMS Cluster is a group of OpenVMS Alpha and OpenVMS VAX systems, storage subsystems, interconnects, and software that work together as one virtual system.

In an OpenVMS Cluster system, each Alpha and VAX node:

- Shares processing resources, queues, and data storage
- Can boot or fail independently
- Runs the OpenVMS operating system

In addition, an OpenVMS Cluster system is managed as a single entity.

Table 1–1 shows the benefits that an OpenVMS Cluster system offers.

Table 1–1  OpenVMS Cluster System Benefits

<table>
<thead>
<tr>
<th>Benefit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource sharing</td>
<td>Multiple systems can access the same storage devices, so that users can share files clusterwide. You can also distribute applications, batch, and print-job processing across multiple systems. Jobs that access shared resources can execute on any system.</td>
</tr>
<tr>
<td>Availability</td>
<td>Data and applications remain available during scheduled or unscheduled downtime of individual systems. A variety of configurations provide many levels of availability up to and including disaster-tolerant operation.</td>
</tr>
<tr>
<td>Flexibility</td>
<td>OpenVMS Cluster computing environments offer compatible hardware and software across a wide price and performance range.</td>
</tr>
<tr>
<td>Scalability</td>
<td>You can add processing and storage resources without disturbing the rest of the system. The full range of systems, from high-end symmetric multiprocessing (SMP) systems to smaller workstations, can be interconnected and easily reconfigured to meet growing needs. You control the level of performance and availability as you expand.</td>
</tr>
<tr>
<td>Ease of management</td>
<td>OpenVMS Cluster management is efficient and secure. Because you manage an OpenVMS Cluster as a single system, many tasks need to be performed only once. OpenVMS Clusters automatically balance user, batch, and print work loads.</td>
</tr>
</tbody>
</table>

</table>
| Adapter    | Devices that connect nodes in an OpenVMS Cluster to interconnects and storage. | The following adapters are used on Peripheral Component Interconnect (PCI) systems:  
  • CIPCA (CI)  
  • KFPSA (DSSI)  
  • KZPSA (SCSI)  
  • DEFPA (FDDI)  
  • DE435 (Ethernet)  
  • KGPSA (Fibre Channel)  
  • DEGPA (Gigabit Ethernet) |

  Reference: See Chapter 4 for more information about adapters. |
| Peripheral devices | Devices that provide input to and produce output from a system. | Peripheral devices include:  
  • Terminals, terminal servers, and modems  
  • Printers, plotters |

1.3 Software Components

OpenVMS Cluster system software can be divided into the following types:

  • OpenVMS operating system components  
  • Networking components  
  • Storage enhancement software  
  • System management software  
  • Business applications

1.3.1 OpenVMS Operating System Components

The operating system manages proper operation of hardware and software components and resources.

Table 1–3 describes the operating system components necessary for OpenVMS Cluster operations. All of these components are enabled by an OpenVMS operating system license or an OpenVMS Cluster license.

Table 1–3 Operating System Components

<table>
<thead>
<tr>
<th>Component</th>
<th>Function</th>

<td>Used with terminal server hardware to support Ethernet-based character cell terminals. During a system failure, LAT software automatically makes a connection to one of the remaining systems.</td>
</tr>
<tr>
<td>Advanced Server for OpenVMS (formerly named PATHWORKS for OpenVMS)</td>
<td>Client and server networking software that links PC systems into OpenVMS Cluster systems.</td>
</tr>
<tr>
<td>Compaq TCP/IP Services for OpenVMS software</td>
<td>Provides Network File System (NFS) server capabilities for OpenVMS and supports Internet networking protocols.</td>
</tr>
</tbody>
</table>

1.3.3 Storage Enhancement Software

Optional storage enhancement software improves the performance or availability of storage subsystems.

Examples include:

- Compaq Volume Shadowing for OpenVMS (redundant arrays of independent disks [RAID] level 1)
- Compaq DECram for OpenVMS (random access memory [RAM] disk)
- StorageWorks RAID Software for OpenVMS (supports RAID level 0 arrays (disk striping) and RAID level 5 arrays (disk striping with parity)
- Compaq Hierarchical Storage Manager (HSM)

For the latest information about StorageWorks products, refer to the StorageWorks web site, which you can select from the Compaq World Wide Web site:

http://www.compaq.com/

1.3.4 System Management Software

System management software helps you manage your OpenVMS Cluster system.

Examples include:

- DIGITAL Availability Manager for Distributed Systems (DECamds) and Compaq Availability Manager

  **Note:** Both DECamds and Availability Manager are provided with the OpenVMS operating system.

- POLYCENTER Capacity Planner
- Compaq Archive/Backup System for OpenVMS
- Compaq Code Management System for OpenVMS
- POLYCENTER Network Manager
1.3.5 Business Applications

Business applications are optional software packages that help you perform your business function.

Examples include:

- Database systems, such as Oracle Rdb, Oracle CDD/Repository, and Sybase
- Transaction processing systems, such as Compaq ACMSxp for OpenVMS Alpha
- Transaction routing systems, such as Reliable Transaction Router

1.4 Configuring an OpenVMS Cluster System

To take advantage of OpenVMS Cluster features and benefits, proper configuration is essential. An ideal OpenVMS Cluster configuration meets the following criteria:

- Provides the best combination of hardware and software components to meet your business requirements.
- Strategically distributes your budget dollars to return maximum value in the areas that are high priority for your business.
- Meets your current needs and retains your investment as your business needs grow and change.

Configuring your OpenVMS Cluster system requires careful planning because you need to consider many factors. You will probably modify plans as new factors arise. As your design evolves, you can weigh advantages against tradeoffs and make decisions that best meet your needs.

1.4.1 General Configuration Rules

The following general rules apply to OpenVMS Cluster systems:

- A node is an OpenVMS system. An OpenVMS Cluster system cannot contain more than 96 Alpha and VAX (combined total) nodes.
- An Alpha and a VAX system can not boot from the same system disk. System disks are architecture specific and can be shared only by systems of the same architecture.
  Cross-architecture satellite booting is supported. Alpha satellites (clients) can boot from a VAX boot server, and VAX satellites (clients) can boot from an Alpha boot server.
- Every OpenVMS node must be able to communicate directly with every other OpenVMS Cluster node.

Configurations that use a shared (multihost) SCSI bus or a shared (multihost) Fibre Channel interconnect must also be configured with any of the other supported OpenVMS Cluster interconnects, because node-to-node communication does not occur across the SCSI bus or the Fibre Channel.

**Reference:** See Section 4.8 for more information about the SCSI interconnect and Section 4.6 for more information about the Fibre Channel interconnect.

Configurations that use a MEMORY CHANNEL interconnect must also be configured with any of the other supported OpenVMS Cluster interconnects for access to storage. Storage cannot be configured on MEMORY CHANNEL.
1.4 Configuring an OpenVMS Cluster System

**Reference:** See Section 4.7 for more information about MEMORY CHANNEL.

- An OpenVMS Cluster node, storage controller, or storage device can participate in only one OpenVMS Cluster system at a time.
- DECnet-Plus software is not required in an OpenVMS Cluster configuration. However, DECnet-Plus is necessary if internode process-to-process communication using DECnet mailboxes is needed. Starting with OpenVMS Version 7.0, the Monitor utility uses a TCP/IP or DECnet transport, as appropriate, for intracluster communication.

In addition to these general rules, more detailed guidelines apply to different configurations. The rest of this manual discusses those guidelines in the context of specific configurations.
Determining Business and Application Requirements

This chapter contains information about how to determine your OpenVMS Cluster business and application requirements.

2.1 Determining Business Requirements

The kinds of business requirements that you have affect the way that you configure your OpenVMS Cluster. Typical business requirements for an OpenVMS Cluster system include:

- Budget
- Availability
- Scalability and future growth
- Physical location requirements
- Security

Some of these requirements may conflict with each other, such as scalability and physical location. For example, you may want to grow your OpenVMS Cluster, but you are limited by physical space or by the location of your systems. In situations like this, determine what your primary requirements are and where you are willing to make tradeoffs.

2.1.1 Budget

As with most business decisions, many of your choices will be determined by cost. Prioritizing your requirements can help you apply your budget resources to areas with the greatest business needs.

When determining your budget, plan for the initial system cost as well as the cost of ownership, which includes:

- Service and update
- Power consumption
- Cooling
- System management
Determining Business and Application Requirements
2.1 Determining Business Requirements

2.1.2 Availability

Determine how available your computing system must be. Most organizations fall into one of the three broad (and sometimes overlapping) categories shown in Table 2–1.

<table>
<thead>
<tr>
<th>Availability Requirements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conventional</td>
<td>For business functions that can wait with little or no effect while a system or application is unavailable.</td>
</tr>
<tr>
<td>24 x 365</td>
<td>For business functions that require uninterrupted computing services, either during essential time periods or during most hours of the day throughout the year. Minimal down time is acceptable.</td>
</tr>
<tr>
<td>Disaster tolerant</td>
<td>For business functions with extremely stringent availability requirements. These businesses need to be immune to disasters like earthquakes, floods, and power failures.</td>
</tr>
</tbody>
</table>

Reference: For more information about availability, see Chapter 8 in this guide.

2.1.3 Scalability and Future Growth

Scalability is the ability to expand an OpenVMS Cluster in any system, storage, and interconnect dimension and at the same time fully use the initial configuration equipment. Scalability at the node level means being able to upgrade and add to your node's hardware and software. Scalability at the OpenVMS Cluster level means being able to increase the capacity of your entire OpenVMS Cluster system by adding processing power, interconnects, and storage across many nodes.

Among the low-end PCs and workstations, midrange departmental systems, and high-end data center systems offered by Digital, each level has different processing, storage, and interconnect characteristics. Investing in the appropriate level means choosing systems that meet and perhaps exceed your current business requirements with some extra capacity to spare. The extra capacity is for future growth, because designing too close to your current needs can limit or reduce the scalability of your OpenVMS Cluster.

If you design with future growth in mind, you can make the most of your initial investment, reuse original equipment, and avoid unnecessary upgrades later.

Reference: See Chapter 10 for more help with analyzing your scalability requirements.

2.1.4 Physical Location Requirements

Physical restrictions can play a key role in how you configure your OpenVMS Cluster. Designing a cluster for a small computer room or office area is quite different from designing one that will be spread throughout a building or across several miles. Power and air-conditioning requirements can also affect configuration design.

You may want to allow room for physical growth and increased power and cooling requirements when designing your cluster.

Reference: See Section 8.6 and Section 10.7.7 for information about multiple and extended local area network (LAN) configurations.
2.1.5 Security

A secure environment is one that limits physical and electronic access to systems by unauthorized users. Most businesses can achieve a secure environment with little or no performance overhead. However, if security is your highest priority, you may need to make tradeoffs in convenience, cost, and performance.

Reference: See the OpenVMS Guide to System Security for more information.

2.2 Determining Application Requirements

Applications require processing power, memory, storage, and I/O resources. Determining your application requirements allows you to design an OpenVMS Cluster system that will meet your application needs. To determine your application requirements, follow the steps described in Table 2–2.

Table 2–2 Determining Your Application Requirements

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Make a list of the applications you currently run or expect to run.</td>
</tr>
<tr>
<td>2</td>
<td>For each application, write down your processor, memory, and I/O requirements (the application documentation provides this information.)</td>
</tr>
<tr>
<td></td>
<td>Processor power must be proportional to the number of calculations your applications perform, with enough additional processor power to oversee data transfer between nodes and between nodes and storage.</td>
</tr>
<tr>
<td></td>
<td>Memory capacity must be sufficient for your applications and for additional OpenVMS Cluster functions. Extra memory frequently improves system performance, so an initial investment in extra memory is probably a good one.</td>
</tr>
<tr>
<td></td>
<td>I/O performance requirements differ among applications. As you choose components such as nodes, interconnects, and adapters, monitor the inherent speed of each component so that you can choose faster components and eliminate potential bottlenecks.</td>
</tr>
<tr>
<td>3</td>
<td>Add up the CPU, memory, and I/O requirements for all of your applications. Add to this sum any special requirements, such as user requirements and peripheral devices.</td>
</tr>
<tr>
<td>4</td>
<td>When you have determined your total application requirements, be sure that your CPU, memory, and I/O resources exceed these requirements by 20%.</td>
</tr>
</tbody>
</table>

2.2.1 Adding Memory

Systems require approximately 5% more memory to run in an OpenVMS Cluster than to run standalone. This additional memory is used to support the shared cluster resource base, which is larger than in a standalone configuration.

With added memory, a node in an OpenVMS Cluster generally can support the same number of users or applications that it supported as a standalone system. As a cluster configuration grows, the amount of memory used for system work by each node may increase. Because the per-node increase depends on both the level of data sharing in the cluster and the distribution of resource management, that increase does not follow fixed rules. If the node is a resource manager for a heavily used resource, additional memory may increase performance for cluster users of that resource.

Reference: For more information about using additional memory to improve performance, refer to the OpenVMS Performance Management manual.
2.2.2 Balancing Processor, Memory, and I/O Resources

Application performance depends on adequate processor, memory, and I/O resources. Depending on your applications, one of these resources may be more important than the others. Consider your application requirements, and find a balance among these three resources that meets your requirements. Table 2-3 provides some guidelines on the resource requirements of different application types.

<table>
<thead>
<tr>
<th>Application Type</th>
<th>Example</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>General timesharing</td>
<td>Program development, document preparation, office automation</td>
<td>Processor and I/O intensive</td>
</tr>
<tr>
<td>Searching and updating a database and displaying reports</td>
<td>Transaction processing, funds transfer, online order entry or reservation systems</td>
<td>I/O and memory intensive</td>
</tr>
<tr>
<td>Simulation, modeling, or calculation</td>
<td>Computer-aided design and manufacturing, image processing, graphics applications</td>
<td>Processor and memory intensive</td>
</tr>
</tbody>
</table>

2.2.3 Tools and Utilities

The OpenVMS operating system supports a number of utilities and tools that help you determine your business and application requirements in OpenVMS Cluster configurations. Table 2-4 describes many of these products and indicates whether each is supplied with the OpenVMS operating system or is an optional product.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Supplied or Optional</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accounting utility</td>
<td>Supplied</td>
<td>Tracks how resources are being used.</td>
</tr>
<tr>
<td>AUTOGEN command procedure</td>
<td>Supplied</td>
<td>Optimizes system parameter settings based on usage.</td>
</tr>
<tr>
<td>DECamds (Digital Availability Manager for Distributed Systems)</td>
<td>Supplied</td>
<td>Collects and analyzes data from multiple nodes simultaneously, directing all output to a centralized DECwindows display. The analysis detects resource availability problems and suggests corrective actions.</td>
</tr>
<tr>
<td>Availability Manager</td>
<td>Supplied</td>
<td>Functionally similar to DECamds but runs on Windows-based systems and on OpenVMS Alpha.</td>
</tr>
<tr>
<td>Monitor utility</td>
<td>Supplied</td>
<td>Provides basic performance data.</td>
</tr>
<tr>
<td>POLYCENTER Capacity Planner</td>
<td>Optional</td>
<td>Provides a capacity-planning function to help analyze how changes in the configuration affect user performance.</td>
</tr>
<tr>
<td>Show Cluster utility</td>
<td>Supplied</td>
<td>Monitors activity and performance in a OpenVMS Cluster configuration.</td>
</tr>
<tr>
<td>DECevent</td>
<td>Supplied</td>
<td>Monitors system and device status and predicts failures.</td>
</tr>
</tbody>
</table>
2.2 Determining Application Requirements

Table 2–4 (Cont.) System Management Tools

<table>
<thead>
<tr>
<th>Tool</th>
<th>Supplied or Optional</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenVMS Management Station</td>
<td>Supplied</td>
<td>Enables system managers to configure and manage user accounts, print queues, and storage across multiple OpenVMS Clusters and OpenVMS nodes. OpenVMS Management Station is a Microsoft Windows and Windows NT based management tool.</td>
</tr>
<tr>
<td>Web-Based Enterprise Services (WEBES)</td>
<td>Supplied</td>
<td>WEBES includes Compaq Analyze, Compaq Crash Analysis Tool (CCAT), DECevent, and the Revision and Configuration Management (RCM) tools. These are the supported tools for all AlphaServer DS, ES, and GS systems running OpenVMS, except for the AlphaServer GS60 and GS140, which must continue to use DECevent.</td>
</tr>
</tbody>
</table>

2.2.4 System Management Tools from OpenVMS Partners

OpenVMS Partners offer a wide selection of tools to meet diverse system management needs, as shown in Table 2–5. The types of tools are described in the following list:

- **Schedule managers**
  Enable specific actions to be triggered at determined times, including repetitive and periodic activities, such as nightly backups.

- **Event managers**
  Monitor a system and report occurrences and events that may require an action or that may indicate a critical or alarming situation, such as low memory or an attempted security breakin.

- **Console managers**
  Enable a remote connection to and emulation of a system console so that system messages can be displayed and commands can be issued.

- **Performance managers**
  Monitor system performance by collecting and analyzing data to allow proper tailoring and configuration of system resources. Performance managers may also collect historical data for capacity planning.

For current information about OpenVMS Partners and the tools they provide, access the OpenVMS web site: http://www.openvms.compaq.com/.

2.2.5 Other Configuration Aids

In addition to these utilities and partner products, several commands are available that allow the system manager to set parameters on HSC, HSJ, HSD, HSZ, HSG, and RF subsystems to help configure the system. See the appropriate hardware documentation for more information.
This chapter provides information to help you select systems for your OpenVMS Cluster to satisfy your business and application requirements.

### 3.1 Alpha and VAX Architectures

An OpenVMS Cluster can include systems running OpenVMS Alpha, OpenVMS VAX, or both. Compaq provides a full range of systems for both the Alpha and VAX architectures.

- **OpenVMS Alpha operating system**
  - Based on a 64-bit RISC (reduced instruction set computing) architecture, OpenVMS Alpha provides industry-leading price/performance benefits with standard I/O subsystems for flexibility and expansion.

- **OpenVMS VAX operating system**
  - Based on a 32-bit CISC (complex instruction set computing) architecture, OpenVMS VAX provides high CISC performance and a rich, powerful instruction set. OpenVMS VAX also supports a wide variety of standard I/O subsystems.

### 3.2 Types of Systems

Alpha and VAX systems span a range of computing environments, including:

- Personal computers (PCs)
- Workstations
- Departmental systems
- Enterprise systems
- Data center systems

### 3.3 Choosing Systems

Your choice of systems depends on your business, your application needs, and your budget. With a high-level understanding of systems and their characteristics, you can make better choices.

Table 3–1 is a comparison of recently shipped OpenVMS Cluster systems. While laptop and personal computers can be configured in an OpenVMS Cluster as client satellites, they are not discussed extensively in this manual. For more information about configuring PCs and laptops, see the Advanced Server for OpenVMS Concepts and Planning Guide.

<td>applications. Data center systems have a high degree of expandability</td>
<td>AlphaServer GS140</td>
</tr>
<tr>
<td></td>
<td>and flexibility and offer the following features:</td>
<td>AlphaServer GS160, GS320</td>
</tr>
<tr>
<td></td>
<td>• Highest CPU and I/O performance</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Ability to support thousands of terminal users, hundreds of PC clients,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>and up to 95 workstations</td>
<td></td>
</tr>
</tbody>
</table>

3.4 Scalability Considerations

When you choose a system based on scalability, consider the following:

• Maximum processor capacity
• Maximum memory capacity
• Maximum storage capacity

The OpenVMS environment offers a wide range of alternative ways for growing and expanding processing capabilities of a data center, including the following:

• Many Alpha and VAX systems can be expanded to include additional memory, processors, or I/O subsystems.
• You can add systems to your OpenVMS Cluster at any time to support increased work load. The vast range of systems, from small workstation to high-end symmetric multiprocessing (SMP) systems, can interconnect and be reconfigured easily to meet growing needs.
• You can add storage to your OpenVMS Cluster system by increasing the quantity and speed of disks, CD-ROM devices, and tapes.

Reference: For more information about storage devices, see Chapter 5.

Reference: For more information about scalability, see Chapter 10.

3.5 Availability Considerations

An OpenVMS Cluster system is a highly integrated environment in which multiple systems share access to resources. This resource sharing increases the availability of services and data. OpenVMS Cluster systems also offer failover mechanisms that are transparent and automatic, and require little intervention by the system manager or the user.

Reference: See Chapter 8 and Chapter 9 for more information about these failover mechanisms and about availability.

3.6 Performance Considerations

The following factors affect the performance of systems:
• Applications and their performance requirements
• The number of users that the system must support
• The type of storage subsystem that you require

With these requirements in mind, compare processor performance, I/O throughput, memory capacity, and disk capacity in the Alpha and VAX specifications that follow.

3.7 System Specifications

The Compaq World Wide Web (WWW) site provides ordering and configuring information for Alpha and Intel workstations and servers. It also contains detailed information about storage devices, printers, and network application support.

To access the Compaq WWW site, use the following URL:

http://www.compaq.com/
Choosing OpenVMS Cluster Interconnects

An interconnect is a physical path that connects computers to other computers, and to storage subsystems. OpenVMS Cluster systems support a variety of interconnects (also referred to as buses) so that members can communicate with each other and with storage, using the most appropriate and effective method available.

The software that enables OpenVMS Cluster systems to communicate over an interconnect is the System Communications Services (SCS). An interconnect that supports node-to-node SCS communications is called a **cluster interconnect**. An interconnect that provides node-to-storage connectivity within a cluster is called a **shared-storage interconnect**. Some interconnects, such as CI and DSSI, can serve as both cluster and storage interconnects.

OpenVMS supports the following types of interconnects:

- **Cluster interconnects** (node to node only)
  - Ethernet (10/100, Gigabit)
  - Asynchronous transfer mode (ATM)
  - FDDI (Fiber Distributed Data Interface)
  - MEMORY CHANNEL
- **Shared-storage interconnects** (node to storage only)
  - Fibre Channel
  - SCSI (Small Computer Systems Interface)
- **Both node-to-node and node-to-storage interconnects**
  - CI (computer interconnect)
  - DSSI (Digital Storage Systems Interconnect)

### 4.1 Characteristics

The interconnects described in this chapter share some general characteristics. Table 4–1 describes these characteristics.
Choosing OpenVMS Cluster Interconnects

4.1 Characteristics

Table 4–1  Interconnect Characteristics

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throughput</td>
<td>The quantity of data transferred across the interconnect. Some interconnects require more processor overhead than others. For example, Ethernet and FDDI interconnects require more processor overhead than do CI or DSSI. Larger packet sizes allow higher data-transfer rates (throughput) than do smaller packet sizes.</td>
</tr>
<tr>
<td>Cable length</td>
<td>Interconnects range in length from 3 m to 40 km.</td>
</tr>
<tr>
<td>Maximum number of nodes</td>
<td>The number of nodes that can connect to an interconnect varies among interconnect types. Be sure to consider this when configuring your OpenVMS Cluster system.</td>
</tr>
<tr>
<td>Supported systems and storage</td>
<td>Each OpenVMS Cluster node and storage subsystem requires an adapter to connect the internal system bus to the interconnect. First consider the storage and processor I/O performance, then the adapter performance, when choosing an interconnect type.</td>
</tr>
</tbody>
</table>

4.2 Comparison of Interconnect Types

Table 4–2 shows key statistics for a variety of interconnects.

</table>

¹Hardware-assisted data link reduces the processor overhead.
²OpenVMS Cluster computers.
⁹Direct-attached SCSI and Fibre Channel storage can be MSCP served over any of the general-purpose cluster interconnects.
¹⁰Based on single-mode fiber, point-to-point link.
¹¹Support for longer distances (up to 100 km) based on inter-switch links (ISLs) using single-mode fiber. In addition, DRM configurations provide longer distance ISLs using the Open Systems Gateway and Wave Division Multiplexors.
¹²Up to 3 OpenVMS Cluster computers, up to 4 with the DWZZH-05 and fair arbitration; up to 15 storage devices.

### 4.3 Multiple Interconnects

You can use multiple interconnects to achieve the following benefits:

- **Failover**
  
  If one interconnect or adapter fails, the node communications automatically move to another interconnect.

- **MSCP server load balancing**
  
  In a multiple MSCP server configuration, an OpenVMS Cluster performs load balancing to automatically choose the best path. This reduces the chances that a single adapter could cause an I/O bottleneck. Depending on your configuration, multiple paths from one node to another node may transfer more information than would a single path.

  **Reference:** See Section 10.7.3 for an example of dynamic MSCP load balancing.

### 4.4 Mixed Interconnects

A mixed interconnect is a combination of two or more different types of interconnects in an OpenVMS Cluster system. You can use mixed interconnects to combine the advantages of each type and to expand your OpenVMS Cluster system. For example, an Ethernet cluster that requires more storage can expand with the addition of Fibre Channel, SCSI, or CI connections.
Choosing OpenVMS Cluster Interconnects
4.5 Interconnects Supported by Alpha and VAX Systems

Table 4–3 shows the OpenVMS Cluster interconnects supported by Alpha and VAX systems.

You can also refer to the most recent OpenVMS Cluster SPD to see the latest information on supported interconnects.

</table>

1 Able to boot over the interconnect as a satellite node.
2 Support for MEMORY CHANNEL Version 2.0 hardware only.
3 Support on AlphaServer 4100 only.

As Table 4–3 shows, OpenVMS Clusters support a wide range of interconnects. The most important factor to consider is how much I/O you need, as explained in Chapter 2.

In most cases, the I/O requirements will be less than the capabilities of any one OpenVMS Cluster interconnect. Ensure that you have a reasonable surplus I/O capacity, then choose your interconnects based on other needed features.

Reference: For detailed information about the interconnects and adapters supported on each AlphaServer system, refer to the Compaq web site:

http://www.compaq.com
Choosing OpenVMS Cluster Interconnects

4.5 Interconnects Supported by Alpha and VAX Systems

Under Products, select Servers, then AlphaServers, then the server family (for example, DS, ES, or GS), then the server model. You can then select from all supported options.

You can also select the Alpha Systems Technology Technical Information web page, from which you can access documentation, supported options, firmware updates, and the software patch service for each Alpha system model.

http://www5.compaq.com/alphaserver/technology/index.html

4.6 Fibre Channel Interconnect

Fibre Channel is a high-performance ANSI standard network and storage interconnect for PCI-based Alpha systems. It is a full-duplex serial interconnect and can simultaneously transmit and receive 100 megabytes per second. For the initial release, Fibre Channel will support simultaneous access of SCSI storage by multiple nodes connected to a Fibre Channel switch. A second type of interconnect is needed for node-to-node communications. Node-to-node communications over Fibre Channel is planned for a future release.

For multihost access to Fibre Channel storage, the following components are required:

- Fibre Channel host adapter (KGPSA-BC, KSPSA-CA)
- Multimode fiber-optic cable (BNGBX-nn), where nn represents distance in meters
- Fibre Channel switch (DSGGA, DSGGB)
- Storage devices that are supported in a multihost configuration (HSG60, HSG80, Modular Data Router [MDR])

4.6.1 Advantages

The Fibre Channel interconnect offers the following advantages:

- High-speed transmission, 1.06 Gb/s
- Scalable configuration to support department to enterprise configurations.
- Long-distance interconnects
  Fibre Channel supports multimode fiber at 500 meters per link. Fibre Channel supports longer-distance interswitch links (ISLs) — up to 100 kilometers per link, using single-mode fiber. In addition, SANworks Data Replication Manager (DRM) configurations provide longer distance ISLs through the use of the Open Systems Gateway and Wave Division Multiplexors.
- High availability
  Multipath support is available to provide configurations with no single point of failure.

4.6.2 Throughput

The Fibre Channel interconnect transmits up to 1.06 Gb/s. It is a full-duplex serial interconnect that can simultaneously transmit and receive 100 MB/s.
Choosing OpenVMS Cluster Interconnects

4.6 Fibre Channel Interconnect

4.6.3 Supported Adapter

The Fibre Channel adapters, the KGPSA and the KSPSA, connect to the PCI bus.

Reference: For complete information about each adapter’s features and order numbers, access the Compaq website at:

http://www.compaq.com/

Under Products, select Servers, then AlphaServers, then the Alpha system of interest. You can then obtain detailed information about all options supported on that system.

4.7 MEMORY CHANNEL Interconnect

MEMORY CHANNEL is a high-performance cluster interconnect technology for PCI-based Alpha systems. With the benefits of very low latency, high bandwidth, and direct memory access, MEMORY CHANNEL complements and extends the unique ability of OpenVMS Clusters to work as a single, virtual system.

Three hardware components are required by a node to support a MEMORY CHANNEL connection:

• A PCI-to-MEMORY CHANNEL adapter
• A link cable (3 m or 10 feet long)
• A port in a MEMORY CHANNEL hub (except for a two-node configuration in which the cable connects just two PCI adapters)

A MEMORY CHANNEL hub is a PC size unit that provides a connection among systems. MEMORY CHANNEL can support up to four Alpha nodes per hub. You can configure systems with two MEMORY CHANNEL adapters in order to provide failover in case an adapter fails. Each adapter must be connected to a different hub.

A MEMORY CHANNEL hub is not required in clusters that comprise only two nodes. In a two-node configuration, one PCI adapter is configured, using module jumpers, as a virtual hub.

4.7.1 Advantages

MEMORY CHANNEL technology provides the following features:

• Offers excellent price/performance.
  With several times the CI bandwidth, MEMORY CHANNEL provides a 100 MB/s interconnect with minimal latency. MEMORY CHANNEL architecture is designed for the industry-standard PCI bus.
• Requires no change to existing applications.
  MEMORY CHANNEL works seamlessly with existing cluster software, so that no change is necessary for existing applications. The new MEMORY CHANNEL drivers, PMDRIVER and MCDRIVER, integrate with the System Communications Services layer of OpenVMS Clusters in the same way that existing port drivers do. Higher layers of cluster software are unaffected.
• Offloads CI, DSSI, and the LAN in SCSI clusters.
  You cannot connect storage directly to MEMORY CHANNEL, but you can use it to make maximum use of each interconnect’s strength.
Choosing OpenVMS Cluster Interconnects

4.7 MEMORY CHANNEL Interconnect

While MEMORY CHANNEL is not a replacement for CI and DSSI, when used in combination with those interconnects, it offloads their node-to-node traffic. This enables them to be dedicated to storage traffic, optimizing communications in the entire cluster.

When used in a cluster with SCSI and LAN interconnects, MEMORY CHANNEL offloads node-to-node traffic from the LAN, enabling it to handle more TCP/IP or DECnet traffic.

- Provides fail-separately behavior.

When a system failure occurs, MEMORY CHANNEL nodes behave like any failed node in an OpenVMS Cluster. The rest of the cluster continues to perform until the failed node can rejoin the cluster.

4.7.2 Throughput

The MEMORY CHANNEL interconnect has a very high maximum throughput of 100 MB/s. If a single MEMORY CHANNEL is not sufficient, up to two interconnects (and two MEMORY CHANNEL hubs) can share throughput.

4.7.3 Supported Adapter

The MEMORY CHANNEL adapter connects to the PCI bus. The MEMORY CHANNEL adapter, CCMAA–BA, provides improved performance over the earlier adapter.

Reference: For complete information about the adapter’s features and order number, access the Compaq website at:

http://www.compaq.com/

Under Products, select Servers, then AlphaServers, then the Alpha system of interest. You can then obtain detailed information about all options supported on that system.

4.8 SCSI Interconnect

The SCSI interconnect is an industry standard interconnect that supports one or more computers, peripheral devices, and interconnecting components. SCSI is a single-path, daisy-chained, multidrop bus. It is a single 8-bit or 16-bit data path with byte parity for error detection. Both inexpensive single-ended and differential signaling for longer distances are available.

In an OpenVMS Cluster, multiple Alpha computers on a single SCSI interconnect can simultaneously access SCSI disks. This type of configuration is called multihost SCSI connectivity. A second type of interconnect is required for node-to-node communication. For multihost access to SCSI storage, the following components are required:

- SCSI host adapter that is supported in a multihost configuration (see Table 4–6)
- SCSI interconnect
- Terminators, one for each end of the SCSI interconnect
- Storage devices that are supported in a multihost configuration (RZnn; refer to the OpenVMS Cluster SPD [29.78.nn])

For larger configurations, the following components are available:

- Storage controllers (HSZnn)
4.8 SCSI Interconnect

- Bus isolators (DWZZA, DWZZB, or DWZZC) to convert single-ended to differential signaling and to effectively double the SCSI interconnect length

Reference: For a detailed description of how to connect SCSI configurations, see Appendix A.

4.8.1 Advantages

The SCSI interconnect offers the following advantages:

- Lowest cost, shared direct access to storage
  Because SCSI is an industry standard and is used extensively throughout the industry, it is available from many manufacturers at competitive prices.

- Scalable configuration to achieve high performance at a moderate price
  You can choose:
  - Width of SCSI interconnect
    Narrow (8 bits) or wide (16 bits).
  - Transmission mode
    Single-ended signaling, the most common and least expensive, or differential signaling, which provides higher signal integrity and allows a longer SCSI interconnect.
  - Signal speed (standard, fast, or ultra mode)
  - Number of nodes sharing the SCSI bus (two or three)
  - Number of shared SCSI buses to which a node can connect (maximum of six)
  - Storage type and size (RZnn or HSZnn)
  - Computer type and size (AlphaStation or AlphaServer)

4.8.2 Throughput

Table 4–4 show throughput for the SCSI interconnect.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Narrow (8-Bit)</th>
<th>Wide (16-Bit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard</td>
<td>5</td>
<td>10</td>
</tr>
<tr>
<td>Fast</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>Ultra</td>
<td>20</td>
<td>40</td>
</tr>
</tbody>
</table>

4.8.3 SCSI Interconnect Distances

The maximum length of the SCSI interconnect is determined by the signaling method used in the configuration and, for single-ended signaling, by the data transfer rate.

There are two types of electrical signaling for SCSI interconnects: single ended and differential. Both types can operate in standard mode, fast mode, or ultra mode. For differential signaling, the maximum SCSI cable length possible is the same for standard mode and fast mode.
Table 4–5 summarizes how the type of signaling method affects SCSI interconnect distances.

### Table 4–5  Maximum SCSI Interconnect Distances

<table>
<thead>
<tr>
<th>Signaling Technique</th>
<th>Rate of Data Transfer</th>
<th>Maximum Cable Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single ended</td>
<td>Standard</td>
<td>6 m$^1$</td>
</tr>
<tr>
<td>Single ended</td>
<td>Fast</td>
<td>3 m</td>
</tr>
<tr>
<td>Single ended</td>
<td>Ultra</td>
<td>20.5 m$^2$</td>
</tr>
<tr>
<td>Differential</td>
<td>Standard or Fast</td>
<td>25 m</td>
</tr>
<tr>
<td>Differential</td>
<td>Ultra</td>
<td>25.5 m$^3$</td>
</tr>
</tbody>
</table>

$^1$The SCSI standard specifies a maximum length of 6 m for this interconnect. However, it is advisable, where possible, to limit the cable length to 4 m to ensure the highest level of data integrity.

$^2$This length is attainable if devices are attached only at each end. If devices are spaced along the interconnect, they must be at least 1 m apart, and the interconnect cannot exceed 4 m.

$^3$More than two devices can be supported.

### 4.8.4 Supported Adapters, Bus Types, and Computers

Table 4–6 shows SCSI adapters with the internal buses and computers they support.

### Table 4–6  SCSI Adapters

<table>
<thead>
<tr>
<th>Adapter</th>
<th>Internal Bus</th>
<th>Supported Computers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Embedded (NCR-810 based)/KZPAA$^1$</td>
<td>PCI</td>
<td>See the options specifications for your system.</td>
</tr>
<tr>
<td>KZPSA$^2$</td>
<td>PCI</td>
<td>Supported on all Alpha computers that support KZPSA in single-host configurations.$^3$</td>
</tr>
<tr>
<td>KZTSA$^2$</td>
<td>TURBOchannel</td>
<td>DEC 3000</td>
</tr>
<tr>
<td>KZPBA-CB$^4$</td>
<td>PCI</td>
<td>Supported on all Alpha computers that support KZPBA in single-host configurations.$^3$</td>
</tr>
</tbody>
</table>

$^1$Single-ended.

$^2$Fast-wide differential (FWD).

$^3$See the system-specific hardware manual.

$^4$Ultra differential. The ultra single-ended adapter (KZPBA-CA) does not support multihost systems.

**Reference:** For complete information about each adapter’s features and order numbers, access the Compaq website at:

http://www.compaq.com/

Under Products, select Servers, then AlphaServers, then the Alpha system of interest. You can then obtain detailed information about all options supported on that system.
Choosing OpenVMS Cluster Interconnects
4.9 CI Interconnect

4.9 CI Interconnect

The CI interconnect is a radial bus through which OpenVMS Cluster systems communicate. It comprises the following components:

- CI host adapter.
- Star coupler—A passive device that serves as a common connection point for signals between OpenVMS nodes and HSC or HSJ controllers that are connected by the CI.
- Optional star coupler expander (CISCE)—Consists of two amplifiers, one for each of its two paths.
- CI cable.

4.9.1 Advantages

The CI interconnect offers the following advantages:

- High speed
  Suitable for larger processors and I/O-intensive applications.
- Efficient access to large amounts of storage
  HSC and HSJ controllers can connect large numbers of disk and tape drives to the OpenVMS Cluster system, with direct access from all OpenVMS nodes on the CI.
- Minimal CPU overhead for communication
  CI adapters are intelligent interfaces that perform much of the work required for communication among OpenVMS nodes and storage. The CI topology allows all nodes attached to a CI bus to communicate directly with the HSC and HSJ controllers on the same CI bus.
- High availability through redundant, independent data paths
  Each CI adapter is connected with two pairs of CI cables. If a single CI cable connection fails, failover automatically occurs.
- Multiple access paths to disks and tapes
  Dual HSC and HSJ controllers and dual-ported devices create alternative paths to storage devices.

4.9.2 Throughput

The CI interconnect has a high maximum throughput. CI adapters use high-performance microprocessors that perform many of the processing activities usually performed by the CPU. As a result, they consume minimal CPU processing power.

Because the effective throughput of the CI bus is high, a single CI interconnect is not likely to be a bottleneck in a large OpenVMS Cluster configuration. If a single CI is not sufficient, multiple CI interconnects can increase throughput.
4.9.3 Supported Adapters and Bus Types

The following are CI adapters and internal buses that each supports:

- CIPCA (PCI/EISA)
- CIXCD (XMI)
- CIBCA-B (VAXBI)

Reference: For complete information about each adapter’s features and order numbers, access the Compaq website at:

http://www.compaq.com/

Under Products, select Servers, then AlphaServers, then the Alpha system of interest. You can then obtain detailed information about all options supported on that system.

4.9.4 Multiple CI Adapters

You can configure multiple CI adapters on some OpenVMS nodes. Multiple star couplers can be used in the same OpenVMS Cluster.

With multiple CI adapters on a node, adapters can share the traffic load. This reduces I/O bottlenecks and increases the total system I/O throughput.

For the maximum number of CI adapters supported on your system, check the options list for your system in your hardware manual or on the AlphaServer web pages.

4.9.5 Configuration Guidelines for CI Clusters

Use the following guidelines when configuring systems in a CI cluster:

- The maximum number of nodes that you can connect to a star coupler is 32. Up to 16 of these nodes can be OpenVMS systems, and the remainder can be HSJ and HSC storage controllers.
- The number of star couplers is limited by the number of CI adapters configured on a system.
- Dual porting of devices between HSJ and HSC controllers is supported as long as they are connected to the same or separate star couplers. Dual porting of devices between HSJ and HSC controllers and local controllers is not supported.
- With the exception of the CIPCA and CIXCD, different types of CI adapters cannot be combined in the same system.
- You can use multiple CI adapters for redundancy and throughput. You can increase throughput by connecting additional CI adapters to separate star couplers; throughput does not increase substantially when you connect a second CI adapter to the same star coupler.

4.10 Digital Storage Systems Interconnect (DSSI)

DSSI is a single-path, daisy-chained, multidrop bus. It provides a single, 8-bit parallel data path with both byte parity and packet checksum for error detection.
4.10 Digital Storage Systems Interconnect (DSSI)

4.10.1 Advantages
DSSI offers the following advantages:
- High reliability
- Shared, direct access to storage at a lower cost than CI
- Direct communication between systems and storage
- High-performance, intelligent storage controllers with embedded caches

4.10.2 Maintenance Consideration
DSSI storage often resides in the same cabinet as the CPUs. For these configurations, the whole system may need to be shut down for service, unlike configurations and interconnects with separately housed systems and storage devices.

4.10.3 Throughput
The maximum throughput is 32 Mb/s.
DSSI has highly intelligent adapters that require minimal CPU processing overhead.

4.10.4 DSSI Adapter Types
There are two types of DSSI adapters:
- Embedded adapter, which is part of the system.
- Optional adapter, which you can purchase separately and add to the system.

4.10.5 Supported Adapters and Bus Types
The following are DSSI adapters and internal bus that each supports:
- KFESA (EISA)
- KFESB (EISA)
- KFPSA (PCI)
- KFMSA (XMI)—VAX only
- KFMSB (XMI)—Alpha only
- KFQSA (Q-bus)
- N710 (embedded)
- SHAC (embedded)
- EDA640 (embedded)

Reference: For complete information about each adapter’s features and order numbers, access the Compaq website at:
http://www.compaq.com/
Under Products, select Servers, then AlphaServers, then the Alpha system of interest. You can then obtain detailed information about all options supported on that system.
4.10 Digital Storage Systems Interconnect (DSSI)

4.10.6 DSSI-Connected Storage

DSSI configurations use HSD intelligent controllers to connect disk drives to an OpenVMS Cluster. HSD controllers serve the same purpose with DSSI as HSJ controllers serve with CI: they enable you to configure more storage.

Alternatively, DSSI configurations use integrated storage elements (ISEs) connected directly to the DSSI bus. Each ISE contains either a disk and disk controller or a tape and tape controller.

4.10.7 Multiple DSSI Adapters

Multiple DSSI adapters are supported for some systems, enabling higher throughput than with a single DSSI bus.

For the maximum number of DSSI adapters supported on a system, check the options list for the system of interest on the AlphaServer web pages.

4.10.8 Configuration Guidelines for DSSI Clusters

The following configuration guidelines apply to all DSSI clusters:

- Each DSSI interconnect can have up to eight nodes attached; four can be systems and the rest can be storage devices. Each of the following counts as a DSSI node:
  - DSSI adapter
  - Any member of the HSDxx family of DSSI and SCSI controllers
  - Any RF, TF, or EF integrated storage element (ISE)

In some cases, physical cabling and termination limitations may restrict the number of systems to two or three that may be connected to a DSSI interconnect. For example:

- Some variants of the DSSI adapter terminate the bus; for example, the N710. For this reason, only two DEC 4000 systems can be configured on a DSSI interconnect.
- The size of a DEC or VAX 10000 system generally limits the number of systems that can be connected to a DSSI interconnect.

- Each DSSI adapter in a single system must be connected to a different DSSI bus.
- Configure VAX 6000, VAX 7000, and VAX 10000 systems with KFMSA adapters.
- Configure DEC 7000 and DEC 10000 systems with KFMSB adapters.
- Configure PCI-based AlphaServer systems with KFPSA adapters. EISA adapters (KFESA/KFESB) adapters can also be configured on most AlphaServer systems, but use of KFPSA is recommended whenever possible.
- Dual porting of devices between HSD controllers is supported as long as they are connected to the same or separate DSSI interconnects. Dual porting of devices between HSD controllers and local controllers is not supported.
- All systems connected to the same DSSI bus must have a common power or ground.

Reference: For more information about DSSI, see the DSSI OpenVMS Cluster Installation and Troubleshooting Manual.
Choosing OpenVMS Cluster Interconnects
4.11 LAN Interconnects

4.11 LAN Interconnects
Ethernet (including Fast Ethernet and Gigabit Ethernet), ATM, and FDDI are LAN-based interconnects. OpenVMS supports LAN emulation over ATM.

These interconnects provide the following features:
- Single-path connections within an OpenVMS Cluster system and a local area network (LAN)
- Support for multiple paths using multiple adapters
- Long-distance interconnect
  In addition to the maximum length specific to each LAN type, as shown in Table 4–2, longer distances can be achieved by bridging between LANs and WAN interswitch links.
- Extended physical distribution of nodes
- Support for multiple clusters (up to 96 nodes each) on a single interconnect

Following the discussion of multiple clusters, information specific to each supported LAN interconnect (Ethernet, ATM, and FDDI) is provided.

4.11.1 Multiple LAN Adapters
Multiple LAN adapters are supported. The adapters can be for different LAN types or for different adapter models for the same LAN type.

Multiple LAN adapters can be used to provide the following:
- Increased node-to-node throughput by distributing the load across multiple LAN paths.
- Increased availability of node-to-node LAN communications.

4.11.1.1 Multiple LAN Path Load Distribution
When multiple node-to-node LAN paths are available, the OpenVMS Cluster software chooses the set of paths to use based on the following criteria, which are evaluated in strict precedence order:

1. Recent history of packet loss on the path
   Paths that have recently been losing packets at a high rate are termed lossy and will be excluded from consideration. Channels that have an acceptable loss history are termed tight and will be further considered for use.

2. Priority
   Management priority values can be assigned to both individual LAN paths and to local LAN devices. A LAN path's priority value is the sum of these priorities. Only tight LAN paths with a priority value equal to, or one less than, the highest priority value of any tight path will be further considered for use.

3. Maximum packet size
   Tight, equivalent-priority channels whose maximum packet size is equivalent to that of the largest packet size of any tight equivalent-priority channel will be further considered for use.
4. Equivalent latency
LAN paths that meet the preceding criteria will be used if their latencies (computed network delay) are closely matched to that of the fastest such channel. The delay of each LAN path is measured using cluster communications traffic on that path. If a LAN path is excluded from cluster communications use because it does not meet the preceding criteria, its delay will be measured at intervals of a few seconds to determine if its delay, or packet loss rate, has improved enough so that it then meets the preceding criteria.

Packet transmissions are distributed in round-robin fashion across all communication paths between local and remote adapters that meet the preceding criteria.

4.11.1.2 Increased LAN Path Availability
Because LANs are ideal for spanning great distances, you may want to supplement an intersite link’s throughput with high availability. You can do this by configuring critical nodes with multiple LAN adapters, each connected to a different intersite LAN link.

A common cause of intersite link failure is mechanical destruction of the intersite link. This can be avoided by path diversity, that is, physically separating the paths of the multiple intersite links. Path diversity helps to ensure that the configuration is unlikely to be affected by disasters affecting an intersite link.

4.11.2 Configuration Guidelines for LAN-Based Clusters
The following guidelines apply to all LAN-based OpenVMS Cluster systems:
• Alpha and VAX systems can be configured with any mix of LAN adapters.
• All LAN paths used for OpenVMS Cluster communication must operate with a minimum of 10 Mb/s throughput and low latency. You must use translating bridges or switches when connecting nodes on one type of LAN to nodes on another LAN type. LAN segments can be bridged to form an extended LAN.
• Multiple, distinct OpenVMS Cluster systems can be configured onto a single, extended LAN. OpenVMS Cluster software performs cluster membership validation to ensure that systems join the correct LAN OpenVMS cluster.

4.11.3 Ethernet (10/100) and Gigabit Ethernet Advantages
The Ethernet (10/100) interconnect is typically the lowest cost of all OpenVMS Cluster interconnects.

Gigabit Ethernet interconnects offer the following advantages in addition to the advantages listed in Section 4.11:
• Very high throughput (1 Gb/s)
• Support of jumbo frames (7552 bytes per frame) for cluster communications

4.11.4 Ethernet (10/100) and Gigabit Ethernet Throughput
The Ethernet technology offers a range of baseband transmission speeds:
• 10 Mb/s for standard Ethernet
• 100 Mb/s for Fast Ethernet
• 1 Gb/s for Gigabit Ethernet
Choosing OpenVMS Cluster Interconnects

4.11 LAN Interconnects

Ethernet adapters do not provide hardware assistance, so processor overhead is higher than for CI or DSSI.

Consider the capacity of the total network design when you configure an OpenVMS Cluster system with many Ethernet-connected nodes or when the Ethernet also supports a large number of PCs or printers. General network traffic on an Ethernet can reduce the throughput available for OpenVMS Cluster communication. Fast Ethernet and Gigabit Ethernet can significantly improve throughput. Multiple Ethernet adapters can be used to improve cluster performance by offloading general network traffic.

Reference: For LAN configuration guidelines, see Section 4.11.2.

4.11.5 Ethernet Adapters and Buses

The following Ethernet adapters and their internal buses are supported in an OpenVMS Cluster configuration:

- DEFTA-xx (TURBOchannel)
- DE2xx (ISA)
- DE425 (EISA)
- DE435 (PCI)
- TULIP (PCI)
- KZPSM (PCI)
- DE450 (PCI)
- DE500-xx (PCI)
- DE600-xx (PCI)
- DE602-xx (PCI)
- DEGPA-xx (PCI)
- 3COM (PCMCIA)
- DEMNA (XMI)
- TGEC (embedded)
- COREIO (TURBOchannel)
- PMAD (TURBOchannel)
- DE422 (EISA)
- DEBNI (VAXBI)
- DEBNA (VAXBI)
- SGEC (embedded)
- TGEC (embedded)
- DESVA (embedded)
- DESQA (Q-bus)
- DELQA (Q-bus)
4.11.6 Ethernet-to-FDDI Bridges and Switches

You can use transparent Ethernet-to-FDDI translating bridges to provide an interconnect between a 10-Mb/s Ethernet segment and a 100-Mb/s FDDI ring. These Ethernet-to-FDDI bridges are also called 10/100 bridges. They perform high-speed translation of network data packets between the FDDI and Ethernet frame formats.

Reference: See Figure 10–21 for an example of these bridges.

You can use switches to isolate traffic and to aggregate bandwidth, which can result in greater throughput.

4.11.7 Configuration Guidelines for Gigabit Ethernet Clusters

Use the following guidelines when configuring systems in a Gigabit Ethernet cluster:

- Two-node Gigabit Ethernet clusters do not require a switch. They can be connected point to point.
- Most Gigabit Ethernet switches can be configured with Gigabit Ethernet or a combination of Gigabit Ethernet and Fast Ethernet (100 Mb/s).
- Each node can have a single connection to the switch or can be configured with multiple paths, thereby increasing availability. The AlphaServer models GS140, 8400, 8200, and 4x00 support up to four adapters each. The AlphaServer models 1200 and 800 support up to two adapters each.
- Support for jumbo frames (7552 bytes each) is available starting with OpenVMS Version 7.3. (Prior to the introduction of jumbo-frame support, the only frame size supported for cluster communications was the standard 1518-byte maximum Ethernet frame size.)
- The DEGPA cannot be used as the boot device, but satellites can be booted over standard 10/100 Ethernet network adapters configured on a Gigabit switch.

4.11.8 ATM Advantages

ATM offers the following advantages, in addition to those listed in Section 4.11:

- High-speed transmission, up to 622 Mb/s
- OpenVMS support for LAN Emulation over ATM allows for the following maximum frame sizes: 1516, 4544 and 9234.
- LAN emulation over ATM provides the ability to create multiple emulated LANs over one physical ATM adapter. Each emulated LAN appears as a separate network. For more information, see the OpenVMS I/O User’s Reference Manual.
Choosing OpenVMS Cluster Interconnects

4.11 LAN Interconnects

- An ATM switch that provides Quality of Service on a per-emulated-LAN basis can be used to favor cluster traffic over other protocols running on different emulated LANs. For more information, see the documentation for your ATM switch.

4.11.9 ATM Throughput

The ATM interconnect transmits up to 622 Mb/s. The adapter that supports this throughput is the DAPCA.

4.11.10 ATM Adapters

ATM adapters supported in an OpenVMS Cluster system and the internal buses on which they are supported are shown in the following list:

- DAPBA (PCI)
- DAPCA (PCI) 351 (PCI)

4.12 Fiber Distributed Data Interface (FDDI)

FDDI is an ANSI standard LAN interconnect that uses fiber-optic or copper cable. FDDI augments the 10 Mb/s Ethernet by providing a high-speed interconnect for multiple Ethernet segments in a single OpenVMS Cluster system.

4.12.1 FDDI Advantages

FDDI offers the following advantages in addition to the LAN advantages listed in Section 4.11:

- Combines high throughput and long distances between nodes
- Supports a variety of topologies

4.12.2 FDDI Node Types

The FDDI standards define the following two types of nodes:

- Stations — The ANSI standard single-attachment station (SAS) and dual-attachment station (DAS) can be used as an interconnect to the FDDI ring. It is advisable to attach stations to wiring concentrators and to attach the wiring concentrators to the dual FDDI ring, making the ring more stable.
- Wiring concentrator — The wiring concentrator (CON) provides a connection for multiple SASs or CONs to the FDDI ring. A DECconcentrator 500 is an example of this device.

4.12.3 FDDI Distance

FDDI limits the total fiber path to 200 km (125 miles). The maximum distance between adjacent FDDI devices is 40 km with single-mode fiber and 2 km with multimode fiber. In order to control communication delay, however, it is advisable to limit the maximum distance between any two OpenVMS Cluster nodes on an FDDI ring to 40 km.
4.12.4 FDDI Throughput

The maximum throughput of the FDDI interconnect (100 Mb/s) is 10 times higher than that of Ethernet.

In addition, FDDI supports transfers using large packets (up to 4468 bytes). Only FDDI nodes connected exclusively by FDDI can make use of large packets.

Because FDDI adapters do not provide processing assistance for OpenVMS Cluster protocols, more processing power is required than for CI or DSSI.

4.12.5 FDDI Adapters and Bus Types

Following is a list of supported FDDI adapters and the buses they support:

- DEFPA (PCI)
- DEFPZ (integral)
- DEMFA (XMI)
- DEFAA (Futurebus+)
- DEFTA (TURBOchannel)
- DEFEA (EISA)
- DEFQA (Q-bus)

Reference: For complete information about each adapter’s features and order numbers, access the Compaq website at:

http://www.compaq.com/

Under Products, select Servers, then AlphaServers, then the Alpha system of interest. You can then obtain detailed information about all options supported on that system.

4.12.6 Storage Servers for FDDI-Based Clusters

FDDI-based configurations use FDDI for node-to-node communication. The HS1xx and HS2xx family of storage servers provide FDDI-based storage access to OpenVMS Cluster nodes.
5. Choosing OpenVMS Cluster Storage Subsystems

This chapter describes how to design a storage subsystem. The design process involves the following steps:

1. Understanding storage product choices
2. Estimating storage capacity requirements
3. Choosing disk performance optimizers
4. Determining disk availability requirements
5. Understanding advantages and tradeoffs for:
   - Cl based storage
   - DSSI based storage
   - SCSI based storage
   - Fibre Channel based storage
   - Host-based storage
   - LAN InfoServer

The rest of this chapter contains sections that explain these steps in detail.

5.1 Understanding Storage Product Choices

In an OpenVMS Cluster, storage choices include the StorageWorks family of products, a modular storage expansion system based on the Small Computer Systems Interface (SCSI–2) standard. StorageWorks helps you configure complex storage subsystems by choosing from the following modular elements:

- Storage devices such as disks, tapes, CD-ROMs, and solid-state disks
- Array controllers
- Power supplies
- Packaging
- Interconnects
- Software
5.1 Understanding Storage Product Choices

5.1.1 Criteria for Choosing Devices

Consider the following criteria when choosing storage devices:

- Supported interconnects
- Capacity
- I/O rate
- Floor space
- Purchase, service, and maintenance cost

5.1.2 How Interconnects Affect Storage Choices

One of the benefits of OpenVMS Cluster systems is that you can connect storage devices directly to OpenVMS Cluster interconnects to give member systems access to storage.

In an OpenVMS Cluster system, the following storage devices and adapters can be connected to OpenVMS Cluster interconnects:

- HSJ and HSC controllers (on the CI)
- HSD controllers and ISEs (on the DSSI)
- HSZ and RZ series (on the SCSI)
- HSG controllers (on the Fibre Channel)
- Local system adapters

Table 5-1 lists the kinds of storage devices that you can attach to specific interconnects.

<table>
<thead>
<tr>
<th>Storage Interconnect</th>
<th>Storage Devices</th>

</tr>
<tr>
<td>Fibre Channel</td>
<td>HSG controllers and SCSI storage</td>
</tr>
<tr>
<td>FDDI</td>
<td>HSxxx controllers and SCSI storage</td>
</tr>
</tbody>
</table>
5.1.3 How Floor Space Affects Storage Choices

If the cost of floor space is high and you want to minimize the floor space used for storage devices, consider these options:

- Choose disk storage arrays for high capacity with small footprint. Several storage devices come in stackable cabinets for labs with higher ceilings.
- Choose high-capacity disks over high-performance disks.
- Make it a practice to upgrade regularly to newer storage arrays or disks. As storage technology improves, storage devices are available at higher performance and capacity and reduced physical size. For example, replacing an HSC95 and SA800 with an HSJ40 and SW800 increases capacity and reduces floor-space consumption.
- Plan adequate floor space for power and cooling equipment.

5.2 Determining Storage Capacity Requirements

Storage capacity is the amount of space needed on storage devices to hold system, application, and user files. Knowing your storage capacity can help you to determine the amount of storage needed for your OpenVMS Cluster configuration.

5.2.1 Estimating Disk Capacity Requirements

To estimate your online storage capacity requirements, add together the storage requirements for your OpenVMS Cluster system's software, as explained in Table 5–2.

<table>

<td></td>
</tr>
<tr>
<td>An extensive user can require a significant amount of storage space for programs under development and data files, in addition to normal system use for electronic mail. This user may require several hundred thousand blocks of storage, depending on the number of projects and programs being developed and maintained.</td>
<td></td>
</tr>
</tbody>
</table>

Total requirements | The sum of the preceding estimates is the approximate amount of disk storage presently needed for your OpenVMS Cluster system configuration.

5.2.2 Additional Disk Capacity Requirements

Before you finish determining your total disk capacity requirements, you may also want to consider future growth for online storage and for backup storage.

For example, at what rate are new files created in your OpenVMS Cluster system? By estimating this number and adding it to the total disk storage requirements that you calculated using Table 5–2, you can obtain a total that more accurately represents your current and future needs for online storage.

To determine backup storage requirements, consider how you deal with obsolete or archival data. In most storage subsystems, old files become unused while new files come into active use. Moving old files from online to backup storage on a regular basis frees online storage for new files and keeps online storage requirements under control.

Planning for adequate backup storage capacity can make archiving procedures more effective and reduce the capacity requirements for online storage.

5.3 Choosing Disk Performance Optimizers

Estimating your anticipated disk performance work load and analyzing the work load data can help you determine your disk performance requirements.

You can use the Monitor utility and DECams to help you determine which performance optimizer best meets your application and business needs.

5.3.1 Performance Optimizers

Performance optimizers are software or hardware products that improve storage performance for applications and data. Table 5–3 explains how various performance optimizers work.
### Table 5–3 Disk Performance Optimizers

<table>
<thead>
<tr>
<th>Optimizer</th>
<th>Description</th>

<tr>
<td>DECram for OpenVMS</td>
<td>A disk device driver that enables system managers to create logical disks in memory to improve I/O performance. Data on an in-memory DECram disk can be accessed at a faster rate than data on hardware disks. DECram disks are capable of being shadowed with Volume Shadowing for OpenVMS and of being served with the MSCP server.1</td>
</tr>
<tr>
<td>Solid-state disks</td>
<td>In many systems, approximately 80% of the I/O requests can demand information from approximately 20% of the data stored on line. Solid-state devices can yield the rapid access needed for this subset of the data.</td>
</tr>
</tbody>
</table>
| Disk striping         | Disk striping (RAID level 0) lets applications access an array of disk drives in parallel for higher throughput. Disk striping works by grouping several disks into a “stripe set” and by dividing the application data into “chunks,” which are spread equally across the disks in the stripe set in a round-robin fashion. By reducing access time, disk striping may improve performance, especially if the application:  
  - Performs large data transfers in parallel.  
  - Requires load balancing across drives.  

  Two independent types of disk striping are available:  
  - Controller-based striping, in which HSJ and HSD controllers combine several disks into a single stripe set. This stripe set is presented to OpenVMS as a single volume. This type of disk striping is hardware based.  
  - Host-based striping, which creates stripe sets on an OpenVMS host. The OpenVMS software breaks up an I/O request into several simultaneous requests that it sends to the disks of the stripe set. This type of disk striping is software based. |
| Extended file cache (XFC) | OpenVMS Alpha Version 7.3 offers improved host-based caching with XFC, which can replace and can coexist with virtual I/O cache (VIOC). XFC is a clusterwide, file-system data cache that offers several features not available with VIOC, including read-ahead caching and automatic resizing of the cache to improve performance. |
| Controllers with disk cache | Some storage technologies use memory to form disk caches. Accesses that can be satisfied from the cache can be done almost immediately and without any seek time or rotational latency. For these accesses, the two largest components of the I/O response time are eliminated. The HSC, HSJ, HSD, and HSZ controllers contain caches. Every RF and RZ disk has a disk cache as part of its embedded controller. |

1The MSCP server makes locally connected disks to which it has direct access available to other systems in the OpenVMS Cluster.

**Reference:** See Section 10.8 for more information about how these performance optimizers increase an OpenVMS Cluster’s ability to scale I/Os.
Choosing OpenVMS Cluster Storage Subsystems

5.4 Determining Disk Availability Requirements

For storage subsystems, availability is determined by the availability of the storage device as well as the availability of the path to the device.

5.4.1 Availability Requirements

Some costs are associated with optimizing your storage subsystems for higher availability. Part of analyzing availability costs is weighing the cost of protecting data against the cost of unavailable data during failures. Depending on the nature of your business, the impact of storage subsystem failures may be low, moderate, or high.

Device and data availability options reduce and sometimes negate the impact of storage subsystem failures.

5.4.2 Device and Data Availability Optimizers

Depending on your availability requirements, choose among the availability optimizers described in Table 5–4 for applications and data with the greatest need.

Table 5–4  Storage Availability Optimizers

<table>
<thead>
<tr>
<th>Availability Optimizer</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redundant access paths</td>
<td>Protect against hardware failures along the path to the device by configuring redundant access paths to the data.</td>
</tr>
<tr>
<td>Volume Shadowing for OpenVMS software</td>
<td>Replicates data written to a virtual disk by writing the data to one or more physically identical disks that form a shadow set. With replicated data, users can access data even when one disk becomes unavailable. If one shadow set member fails, the shadowing software removes the drive from the shadow set, and processing continues with the remaining drives. Shadowing is transparent to applications and allows data storage and delivery during media, disk, controller, and interconnect failure. A shadow set can contain up to three members, and shadow set members can be anywhere within the storage subsystem of an OpenVMS Cluster system. Reference: See Volume Shadowing for OpenVMS for more information about volume shadowing.</td>
</tr>
<tr>
<td>System disk redundancy</td>
<td>Place system files judiciously on disk drives with multiple access paths. OpenVMS Cluster availability increases when you form a shadow set that includes the system disk. You can also configure an OpenVMS Cluster system with multiple system disks. Reference: For more information, see Section 11.2.</td>
</tr>
<tr>
<td>Database redundancy</td>
<td>Keep redundant copies of certain files or partitions of databases that are, for example, updated overnight by batch jobs. Rather than using shadow sets, which maintain a complete copy of the entire disk, it might be sufficient to maintain a backup copy on another disk or even on a standby tape of selected files or databases.</td>
</tr>
<tr>
<td>DECEvent</td>
<td>DECEvent, in conjunction with volume shadowing, can detect most imminent device failures with sufficient lead time to move the data to a spare device. Enhance device reliability with appropriate software tools. Use device-failure prediction tools, such as DECEvent, where high availability is needed. (continued on next page)</td>
</tr>
</tbody>

<tr>
<td>Newer devices</td>
<td>Protect against failure by choosing newer devices. Typically, newer devices provide improved reliability and mean time between failures (MTBF). Newer controllers also improve reliability by employing updated chip technologies.</td>
</tr>
<tr>
<td>Implement thorough backup strategies</td>
<td>Frequent and regular backups are the most effective way to ensure the availability of your data.</td>
</tr>
</tbody>
</table>

5.5 CI Based Storage

The CI interconnect provides the highest OpenVMS Cluster availability with redundant, independent transmit-and-receive CI cable pairs. The CI offers multiple access paths to disks and tapes by means of dual-ported devices between HSC or HSJ controllers.

5.5.1 Supported Controllers and Devices

The following controllers and devices are supported by the CI interconnect:

- HSJ storage controllers
  - SCSI devices (RZ, TZ, EZ)
- HSC storage controllers
  - SDI and STI devices (RA, ESE, TA)
  - K.SCSI devices (RZ, TZ, EZ)

5.6 DSSI Storage

DSSI-based configurations provide shared direct access to storage for systems with moderate storage capacity. The DSSI interconnect provides the lowest-cost shared access to storage in an OpenVMS Cluster.

The storage tables in this section may contain incomplete lists of products.

5.6.1 Supported Devices

DSSI configurations support the following devices:

- EF-series solid-state disks
- RF-series disks
- TF-series tapes
- DECarray storage arrays
- HSD storage controller
  - SCSI devices (RZ, TZ, EZ)

Reference: RZ, TZ, and EZ SCSI storage devices are described in Section 5.7.
5.7 SCSI-Based Storage

The Small Computer Systems Interface (SCSI) bus is a storage interconnect based on an ANSI industry standard. You can connect up to a total of 8 or 16 nodes (3 of which can be CPUs) to the SCSI bus.

5.7.1 Supported Devices

The following devices can connect to a single host or multihost SCSI bus:

- RZ-series disks
- HSZ storage controllers

The following devices can connect only to a single host SCSI bus:

- EZ-series disks
- RRD-series CD-ROMs
- TZ-series tapes

5.8 Fibre Channel Based Storage

The Fibre Channel interconnect is a storage interconnect that is based on an ANSI industry standard.

5.8.1 Storage Devices

The HSG storage controllers can connect to a single host or to a multihost Fibre Channel interconnect.

5.9 Host-Based Storage

Host-based storage devices can be connected locally to OpenVMS Cluster member systems using local adapters. You can make this locally connected storage available to other OpenVMS Cluster members by configuring a node as an MSCP server.

You can use local adapters to connect each disk to two access paths (dual ports). Dual porting allows automatic failover of disks between nodes.

5.9.1 Internal Buses

Locally connected storage devices attach to a system's internal bus. Alpha systems use the following internal buses:

- PCI
- EISA
- XMI
- SCSI
- TURBOchannel
- Futurebus+

VAX systems use the following internal buses:

- VAXBI
- XMI
- Q-bus
Choosing OpenVMS Cluster Storage Subsystems
5.9 Host-Based Storage

• SCSI

5.9.2 Local Adapters

Following is a list of local adapters and their bus types:

• KGPSA (PCI)
• KZPSM (PCI)
• KZPDA (PCI)
• KZPSC (PCI)
• KZPAC (PCI)
• KZE (EISA)
• KZM (XMI)
• PB2HA (EISA)
• PMAZB (TURBOchannel)
• PMAZC (TURBOchannel)
• KD (XMI)
• KDB50 (VAXBI)
• KDA50 (Q-bus)
This chapter describes multipath SCSI support, which is available on OpenVMS Alpha, starting with Version 7.2. The SCSI protocol is used on both the parallel SCSI interconnect and the Fibre Channel interconnect. The term **SCSI** is used to refer to either parallel SCSI or Fibre Channel (FC) devices throughout the chapter.

**Note**

Failover between a local path to a SCSI device and an MSCP-served path to that same device is not supported at this time. The default setting of the MPDEV_REMOTE system parameter (MPDEV_REMOTE = 0) in OpenVMS Version 7.3 turns off this type of failover. (Although failover to an MSCP path is not supported, multipath devices can be MSCP served to other systems in an OpenVMS Cluster system.)

This SCSI multipath feature may be incompatible with some third-party disk caching, disk shadowing, or similar products. Compaq advises that you not use such software on SCSI devices that are configured for multipath failover (for example, SCSI devices that are connected to HSZ70 and HSZ80 controllers in multibus mode) until this feature is supported by the producer of the software.

Refer to Section 6.2 for important requirements and restrictions for using the multipath SCSI function.

Note that the Fibre Channel and parallel SCSI interconnects are shown generically in this chapter. Each is represented as a horizontal line to which the node and storage subsystems are connected. Physically, the Fibre Channel interconnect is always radially wired from a switch, as shown in Figure 7–1. Parallel SCSI can be radially wired to a hub or can be a daisy-chained bus.

The representation of multiple SCSI disks and SCSI buses in a storage subsystem is also simplified. The multiple disks and SCSI buses, which one or more HSZx or HSGx controllers serve as a logical unit to a host, are shown in the figures as a single logical unit.

The following topics are presented in this chapter:

- Overview of multipath SCSI support (Section 6.1)
- Configuration requirements and restrictions (Section 6.2)
- HSx failover modes (Section 6.3)
- Parallel SCSI multipath configurations (Section 6.4)
6.1 Overview of Multipath SCSI Support

A multipath SCSI configuration provides failover from one path to a device to another path to the same device. Multiple paths to the same device increase the availability of that device for I/O operations. Multiple paths also offer higher aggregate performance. Figure 6–1 shows a multipath SCSI configuration. Two paths are configured from a computer to the same virtual storage device.

Multipath SCSI configurations can use either parallel SCSI or Fibre Channel as the storage interconnect, as illustrated by Figure 6–1.

Two or more paths to a single device are called a multipath set. When the system configures a path to a device, it checks for an existing device with the same name but a different path. If such a device is found, and multipath support is enabled, the system either forms a multipath set or adds the new path to an existing set. If multipath support is not enabled, then no more than one path to a device is configured.

The system presents a multipath set as a single device. The system selects one path to the device as the “current” path, and performs all I/O over this path until there is a failure or the system manager requests that the system switch to another path.

Multipath SCSI support provides two types of failover:

- Direct SCSI to direct SCSI
- Direct SCSI to MSCP served

Direct SCSI to direct SCSI failover requires the use of multiported SCSI devices. Direct SCSI to MSCP served failover requires multiple hosts per SCSI bus, but does not require multiported SCSI devices. These two failover types can be combined. Each type and the combination of the two are described next.

6.1.1 Direct SCSI to Direct SCSI Failover

Direct SCSI to direct SCSI failover can be used on systems with multiported SCSI devices. The dual HSZ70, the HSZ80 and the HSG80 are examples of multiported SCSI devices. A multiported SCSI device can be configured with multiple ports on the same physical interconnect so that if one of the ports fails, the host can continue to access the device through another port. This is known as transparent failover mode and has been supported by OpenVMS since Version 6.2.

OpenVMS Version 7.2 introduced support for a new failover mode in which the multiported device can be configured with its ports on different physical interconnects. This is known as multibus failover mode.

The HSx failover modes are selected by HSx console commands. Transparent and multibus modes are described in more detail in Section 6.3.
Figure 6–1 is a generic illustration of a multibus failover configuration.

Note

Configure multiple direct SCSI paths to a device only when multipath support is enabled on all connected nodes, and the HSZ/G is in multibus failover mode.

The two logical disk devices shown in Figure 6–1 represent virtual storage units that are presented to the host by the HSx controller modules. Each logical storage unit is “on line” to one of the two HSx controller modules at a time. When there are multiple logical units, they can be on line to different HSx controllers so that both HSx controllers can be active at the same time.

In transparent mode, a logical unit switches from one controller to the other when an HSx controller detects that the other controller is no longer functioning.

In multibus mode, as shown in Figure 6–1, a logical unit switches from one controller to the other when one of the following events occurs:

• One HSx controller detects that the other controller is no longer functioning.
• The OpenVMS multipath software detects that the current path has failed and issues a command to cause a switch.
• The OpenVMS system manager issues a command to cause a switch.

Figure 6–1  Multibus Failover Configuration

Note the following about Figure 6–1:

• Host has two adapters.
• Interconnects can both be parallel SCSI (HSZ70 or HSZ80) or both be Fibre Channel (HSG80) but not mixed.
6.1 Overview of Multipath SCSI Support

- Storage cabinet contains two HSx controllers configured for multibus failover mode.

The multibus configuration offers the following advantages over transparent failover:
- Higher aggregate performance with two host adapters and two HSx controller modules in operation.
- Higher availability because the storage is still accessible when a host adapter, the interconnect, or the HSx controller module on a path fails.

6.1.2 Direct SCSI to MSCP Served Failover

Note

The feature described in this section is not supported in OpenVMS Version 7.3. This feature is planned for a future release.

OpenVMS provides support for multiple hosts that share a SCSI bus. This is known as a multihost SCSI OpenVMS Cluster system. In this configuration, the SCSI bus is a shared storage interconnect. Cluster communication occurs over a second interconnect (LAN, DSSI, CI, or MEMORY CHANNEL).

Multipath support in a multihost SCSI OpenVMS Cluster system enables failover from directly attached SCSI storage to MSCP served SCSI storage, as shown in Figure 6–2.

Figure 6–2 Direct SCSI to MSCP Served Configuration With One Interconnect

Note the following about this configuration:
- Two hosts are connected to a shared storage interconnect.
- Two hosts are connected by a second interconnect (LAN, CI, DSSI, or MEMORY CHANNEL) for cluster communications.
- The storage devices can have a single port or multiple ports.
• If node Edgar’s SCSI connection to the storage fails, the SCSI storage is
MSCP served by the remaining host over the cluster interconnect.

6.1.3 Configurations Combining Both Types of Multipath Failover

In a multihost SCSI OpenVMS cluster system, you can increase storage
availability by configuring the cluster for both types of multipath failover
(direct SCSI to direct SCSI and direct SCSI to MSCP served SCSI), as shown in
Figure 6–3.

Note

Failover from directly connected storage to MSCP served storage is not
supported in OpenVMS Version 7.3. This feature is planned for a future
release.

Figure 6–3 Direct SCSI to MSCP Served Configuration With Two Interconnects

Note the following about this configuration:
• Both nodes are directly connected to both storage interconnects.
• Both nodes are connected to a second interconnect for cluster communications.
• Each HSx storage controller is connected to only one interconnect.
• Both HSx storage controllers are in the same cabinet.

This configuration provides the advantages of both direct SCSI failover and direct
to MSCP served failover.
6.2 Configuration Requirements and Restrictions

The requirements for multipath SCSI and FC configurations are presented in Table 6–1.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host adapter</td>
<td>For parallel SCSI, the KZPBA-CB must be used. It is the only SCSI host adapter that supports multipath failover on OpenVMS.</td>
</tr>
<tr>
<td>Alpha console firmware</td>
<td>For systems with HSZ70 and HSZ80, the minimum revision level is 5.3 or 5.4, depending on your AlphaServer. For systems with HSG80, the minimum revision level is 5.4</td>
</tr>
<tr>
<td>Controller firmware</td>
<td>For HSZ70, the minimum revision level is 7.3; for HSZ80, it is 8.3; for HSG80, it is 8.4.</td>
</tr>
<tr>
<td>Controller module mode</td>
<td>Must be set to multibus mode. The selection is made at the H5x console.</td>
</tr>
</tbody>
</table>
| Full connectivity          | All hosts that are connected to an H5x in multibus mode must have a path to both H5x controller modules. This is because hosts that are connected exclusively to different controllers will switch the logical unit back and forth between controllers, preventing any I/O from executing. To prevent this from happening, always provide full connectivity from hosts to controller modules. If a host's connection to a controller fails, then take one of the following steps to avoid indefinite path switching:
   • Repair the connection promptly.
   • Prevent the other hosts from switching to the partially-connected controller. This is done by either disabling switching to the paths that lead to the partially-connected controller (see Section 6.7.10), or by shutting down the partially-connected controller.
   • Disconnect the partially-connected host from both controllers. |
| Allocation classes         | For parallel SCSI, a valid HSZ allocation class is required (refer to Section 6.5.3). If a SCSI bus is configured with HSZ controllers only, and all the controllers have a valid HSZ allocation class, then it is not necessary to adhere to the older SCSI device naming rules for that bus. That is, the adapters do not require a matching port allocation class, or a matching node allocation class and matching OpenVMS adapter device names. However, if there are non-HSZ devices on the bus, or HSZ controllers without an HSZ allocation class, then the standard rules for node and port allocation class assignments and controller device names for shared SCSI buses must be followed. Booting from devices with an HSZ allocation class is supported on all AlphaServers that support the KZPBA-CB except for the AlphaServer 2x00(A). The allocation class is not used for FC devices. |

The restrictions for multipath FC and SCSI configurations are presented in Table 6–2.
Table 6–2 Multipath FC and SCSI Configuration Restrictions

<td>SCSI to MSCP failover</td>
<td>In OpenVMS Version 7.3, the MSCP path can not be included in the multipath set. This is accomplished by setting the SYSGEN parameter MPDEV_REMOTE to 0, which is currently the default setting. This restriction will be removed later.</td>
</tr>
</tbody>
</table>

6.3 HSx Failover Modes

The HSZ70, HSZ80, and HSG80 implement two modes of failover operation when they are in a dual-redundant configuration, transparent failover mode and multibus failover mode.

Note

OpenVMS requires that the HSG60 or HSG80 be in multibus failover mode. OpenVMS does not support transparent mode for the HSG60 or HSG80.

For the system to operate correctly, the HSx failover mode must be compatible with the configuration of the interconnect hardware and the host operating system software, as described in the following sections.

6.3.1 Transparent Failover Mode

In transparent failover mode, the HSZ presents each logical unit on one port of the dual controller pair. Different logical units may be assigned to different ports, but an individual logical unit is accessible through one port at a time. When the HSZ detects that a controller module has failed, it moves the logical unit to the corresponding port on the surviving controller, as shown in Figure 6–4.
The assumption in transparent mode is that the two ports are on the same host bus, so the logical unit can move from one port to the other without requiring any changes to the host's view of the device. The system manager must ensure that the bus configuration is correct for this mode of failover. Transparent failover has been supported by OpenVMS since Version 6.2.

To select transparent failover mode, enter one of the following commands at the HSZ console, depending on your configuration:

`HSZ> SET FAILOVER COPY=THIS_CONTROLLER`

or

`HSZ> SET FAILOVER COPY=OTHER_CONTROLLER`

An example of the output of a console SHOW command on an HSZ in transparent mode follows:

```
z70_A => SHOW THIS_CONTROLLER
Controller:
    HSZ70 ZG64100160 Firmware XB32-0, Hardware CX25
    Configured for dual-redundancy with ZG64100136
    In dual-redundant configuration
    Device Port SCSI address 7
    Time: 02-DEC-1998 09:22:09
Host port:
    SCSI target(s) (0, 2, 3, 4, 5, 6)
    Preferred target(s) (3, 5)
    TRANSFER_RATE_REQUESTED = 20MHZ
    Host Functionality Mode = A
    Allocation class 0
    Command Console LUN is target 0, lun 1
Cache:
    32 megabyte write cache, version 4
    Cache is GOOD
    Battery is GOOD
    No unflushed data in cache
    CACHE_FLUSH_TIMER = DEFAULT (10 seconds)
    NOCACHE_UPS
```
6.3.2 Multibus Failover Mode

In multibus failover mode, the HSx responds to SCSI Inquiry commands from the host on all ports of the dual controller pair. This allows the host to be aware of all the possible paths to the device. There are two advantages to having the host aware of all the paths to a device:

- The host can select an alternate path if it detects a failure on the current path. This is in addition to the failover that occurs when the HSx controller detects a failure, as is provided in transparent mode.
- The paths do not need to be on the same host bus. When the host is aware of the alternate paths, it can adjust its addressing methods appropriately to select a different path. This removes the SCSI bus as a single point of failure.

Note that, although the logical unit is visible on all ports, it is on line and thus capable of doing I/O on the ports of only one controller at a time. Different logical units may be on line to different controllers, but an individual logical unit is on line to only one controller at a time, as shown in Figure 6–5.

**Figure 6–5 Storage Subsystem in Multibus Mode**

D44 answers SCSI Inquiry commands on all four ports.

D44 does I/O on these two ports.

You can determine which controller a logical unit is on line to by entering the HSx console command, as follows:

```
z70_A => SHOW UNIT FULL
LUN Uses
--------------------------------------------------------------
D200 DISK20300
Switches:                                                                 |
          NONWRITE_PROTECT      READ_CACHE
          MAXIMUM_CACHED_TRANSFER_SIZE = 32
          ACCESS_ID = ALL
State:                                                                 |
          ONLINE to the other controller
          PREFERRED_PATH = OTHER_CONTROLLER
Size: 2050860 blocks
```

The host executes I/O to a logical unit on one path at a time, until that path fails. If a controller has two ports, as the HSZ80 and the HSG80 controllers do, then different hosts can access the same logical unit over different ports of the controller to which the logical unit is online.

An HSx in multibus failover mode can only be used with the multipath functionality introduced in OpenVMS Version 7.2.
Configuring Multiple Paths to SCSI and Fibre Channel Storage

6.3 HSx Failover Modes

To select multibus failover mode, enter one of the following commands at the HSx: console, whichever is appropriate to your configuration:

```
HSZ> SET MULTIBUS_FAILOVER COPY=THIS_CONTROLLER
```

or

```
HSZ> SET MULTIBUS_FAILOVER COPY=OTHER_CONTROLLER
```

An example of the output of a console SHOW command on an HSx controller in multibus mode follows:

```
z70_B => SHOW THIS_CONTROLLER

```

6.3.3 Port Addressing for Controllers in Multibus Mode

There is a difference between parallel SCSI and FC in the way that the ports on multibus controllers are addressed. In parallel SCSI (the HSZ70 and the HSZ80), all the ports are assigned the same SCSI target IDs. This is noted for the HSZ80 configuration shown in Figure 6–6.

**Figure 6–6  Port Addressing for Parallel SCSI Controllers in Multibus Mode**

D44 answers SCSI Inquiry commands on all four ports.

All four ports have the same SCSI target ID. They must be on separate SCSI buses.

The reason all the ports have the same target ID is that the target ID is part of the OpenVMS device name (for example, the 6 in $4$DKC600), and the device name must be the same for all paths. This means that each port must be on a separate SCSI bus or there will be an address conflict.
In Fibre Channel configurations with the HSG80, all the ports have their own FC address and WWID, as noted in Figure 6–7.

Figure 6–7  Port Addressing for Fibre Channel Controllers in Multibus Mode

D44 answers SCSI Inquiry commands on all four ports.

All four ports have different FC addresses and WWIDs. The port can be on the same or different FC interconnects.

The ports on the HSG80 have separate FC addresses and WWIDs because these items are not used in the OpenVMS FC device name. This means that any number of ports can be connected to the same FC interconnect. In fact, all the ports of the HSG80 in multibus mode should be connected, even if there is just one interconnect, because this can improve availability and performance.

6.4 Parallel SCSI Multipath Configurations

The figures in this section show systems configured for transparent failover and for multipath failover. The special considerations for controller modules that have multiple ports, such as the HSZ80, are also described.

6.4.1 Transparent Failover

Transparent failover in a parallel SCSI configuration, as shown in Figure 6–8, requires that both controller modules be on the same SCSI bus.
In this configuration:

- Each logical unit is visible to the host on only one controller module at a time. The other controller module does not answer at the same SCSI address, but it can be used for other SCSI addresses.
- One HSZ controller module detects the failure of the other controller and fails over the logical unit to itself. The surviving controller takes over the SCSI address or addresses of the failed controller.

### 6.4.2 Multibus Failover and Multiple Paths

A parallel SCSI configuration with multiple paths from the host to storage offers higher availability and performance than a configuration using transparent failover. Figure 6–9 shows this configuration.
Note the following about this configuration:

- Each logical unit is visible to the host at the same ID on both controller modules so it can be configured. The logical unit responds to read/write I/O on only one controller at a time, the controller to which it is “online”.

- The controller modules must be on different SCSI buses to prevent a bus ID conflict.

- The HSZ moves a logical unit to the other controller if either of the following events occurs:
  - HSZ detects a controller failure.
  - Host sends a SCSI START command for the logical unit to the other controller.

### 6.4.3 Configurations Using Multiported Storage Controllers

Higher levels of availability and performance can be achieved with the use of multiported storage controllers, such as the HSZ80. The HSZ80 storage controller is similar to the HSZ70 except that each HSZ80 controller has two ports.

This section shows three configurations that use multiported storage controllers. The configurations are presented in order of increasing availability.

Figure 6–10 shows a single host with a single interconnect, using an HSZ80 in transparent mode.
Figure 6–10 Multiported Parallel SCSI Configuration With Single Interconnect in Transparent Mode

Note the following about this configuration:
- Each logical unit is visible on one port per storage controller.
- If a port fails, the HSZ80 fails over the traffic to the corresponding port of the other HSZ80.

Figure 6–11 shows a system configured in transparent mode using two paths from the host.

Figure 6–11 Multiported Parallel SCSI Configuration With Multiple Paths in Transparent Mode

In this configuration:
- Physically corresponding ports must be on the same SCSI bus.
- A maximum of two buses can be connected to each storage controller.
Configuring Multiple Paths to SCSI and Fibre Channel Storage

6.4 Parallel SCSI Multipath Configurations

Note that in this configuration, although there are two buses, there is only one path from the host to a particular logical unit. When a controller fails, the logical unit moves to the corresponding port on the other controller. Both ports are on the same host bus.

This configuration has better performance than the one in Figure 6–10 because both SCSI buses can be simultaneously active. This configuration does not have higher availability, however, because there is still only one path from the host to the logical unit.

Figure 6–12 shows a system using the multiported HSZ80 storage controller configured in multibus mode.

**Figure 6–12 Multiported Parallel SCSI Configuration With Multiple Paths in Multibus Mode**

In this configuration:
- Each logical unit is visible to the host at the same ID on all ports (so they all will be configured by the host).
- All the ports must be on different SCSI buses.
- The host uses one path at a time.
- Each logical unit can execute I/O simultaneously over the two ports of the controller to which it is “on line.” This means that if there are multiple hosts, then two paths to the storage device may be simultaneously active.

6.5 Device Naming for Parallel SCSI Multipath Configurations

SCSI device names have evolved as systems have become larger and more complex. At first, SCSI device names were entirely path dependent. The device name indicated the node, host adapter, SCSI bus ID, and logical unit number (LUN) used to access the device. Path-based names are not suitable for multiple host and multiple path environments because:
6.5 Device Naming for Parallel SCSI Multipath Configurations

- The node name can not be used when there are multiple nodes with direct access to a device.
- The host adapter’s controller letter can not be used when the controller letters on a shared bus do not match.
- The host adapter’s controller letter can not be used when a node is connected to a device with multiple adapters.

The first two of these issues were addressed by the use of the node allocation class and the port allocation class. The third issue requires the introduction of an HSZ controller-based allocation class. These three allocation classes are reviewed in the following sections.

6.5.1 Review of Node Allocation Classes

A node allocation class is used in a device name in place of a node name. A node allocation class is needed to produce a unique device name when multiple nodes have a direct connection to the same SCSI device.

A node allocation class can only be used in a device name when all nodes that share access to a SCSI storage device:

- Have only one direct path to the device.
- Use the same host controller name on the shared bus.
- Have sufficient SCSI IDs to produce unique names for nonshared devices.

Figure 6–13 shows a configuration whose devices are named using a node allocation class.

![Figure 6–13 Devices Named Using a Node Allocation Class](image)

6.5.2 Review of Port Allocation Classes

A port allocation class in a device name designates the host adapter that is used to access the device. The port allocation class replaces the node allocation class in the device name, and the adapter controller letter is set to the constant A.

The port allocation class can be used when SCSI systems need more SCSI IDs to produce unique device names, or when the controller letter of the adapters on a shared bus do not match. A port allocation class can only be used in a device name when all nodes that share access to a SCSI storage device have only one direct path to the device.
Figure 6–14 shows a configuration whose devices are named using a port allocation class.

**Figure 6–14 Devices Named Using a Port Allocation Class**

![Diagram showing devices named using port allocation class](image)

### 6.5.3 Device Naming Using HSZ Allocation Classes

When any node has multiple buses connecting to the same storage device, the new HSZ allocation class shown in Figure 6–15 must be used.

**Figure 6–15 Devices Named Using an HSZ Allocation Class**

![Diagram showing devices named using HSZ allocation class](image)

An HSZ allocation class is similar to the HSC, HSD, and HSJ allocation classes. The device name, using an HSZ allocation class number, takes the following form:

```
$HSZ-allocation-class$ddcu
```

where:

- **HSZ-allocation-class** is a decimal value from 1 to 999, assigned to a particular HSZ storage controller by the system manager.
Confi
figuring Multiple Paths to SCSI and Fibre Channel Storage

6.5 Device Naming for Parallel SCSI Multipath Configurations

- dd represents the device class, which is DK for disk
- c represents the controller, which must be A when using an HSZ allocation class
- u represents the device unit number, which is determined by the SCSI bus ID and the logical unit number (LUN) of the device

The system manager sets an HSZ allocation class from the HSZ console, using one of the following commands, as appropriate to the configuration:

```
HSZ> SET THIS_CONTROLLER ALLOCATION_CLASS = n
```

or

```
HSZ> SET OTHER_CONTROLLER ALLOCATION_CLASS = n
```

where n is a value from 1 to 999.

When the allocation class is set on one controller module in a dual redundant configuration, it is automatically set to the same value on the other controller.

In the following example, the allocation class is set to 199. The example shows that the value is set for both controllers.

```
z70_B => SET THIS ALLOCATION_CLASS=199
z70_B => SHOW THIS_CONTROLLER
Controller:
    HSZ70 ZG64100136 Firmware XB32-0, Hardware CX25
    Configured for MULTIBUS_FAILOVER with ZG64100160
        In dual-redundant configuration
    Device Port SCSI address 6
    Time: NOT SET
Host port:
    SCSI target(s) (0, 2, 3, 4, 5, 6)
    TRANSFER_RATE_REQUESTED = 20MHZ
    Host Functionality Mode = A
    Allocation class 199
    Command Console LUN is target 0, lun 1
Cache:
    32 megabyte write cache, version 4
    Cache is GOOD
    Battery is GOOD
    No unflushed data in cache
    CACHE_FLUSH_TIMER = DEFAULT (10 seconds)
    NOCACHE_UPS
z70_B => SHOW OTHER_CONTROLLER
Controller:
    HSZ70 ZG64100160 Firmware XB32-0, Hardware CX25
    Configured for MULTIBUS_FAILOVER with ZG64100136
        In dual-redundant configuration
    Device Port SCSI address 7
    Time: NOT SET
Host port:
    SCSI target(s) (0, 2, 3, 4, 5, 6)
```
6.5 Device Naming for Parallel SCSI Multipath Configurations

TRANSFER_RATE_REQUESTED = 20MHZ
Host Functionality Mode = A
Allocation class 199
Command Console LUN is target 0, lun 1
Cache:
   32 megabyte write cache, version 4
   Cache is GOOD
   Battery is GOOD
   No unflushed data in cache
   CACHE_FLUSH_TIMER = DEFAULT (10 seconds)
   NOCACHE_UPS

The following rules pertain to the use of an HSZ allocation class in SCSI device names:

1. In multibus mode, an HSZ allocation class must be used in a device name (otherwise, the device is not configured).
2. In transparent mode, an HSZ allocation class can be used in a device name but it is not required.
3. The HSZ allocation class number must be the same for both controllers of an HSZ. This is handled automatically by the HSZ firmware.
4. The HSZ allocation class number must be unique among all types of allocation classes throughout the cluster.
5. The HSZ allocation class must be specified when referring to devices that have an HSZ allocation class. For example, the names DKA500 and NODE10$DKA500 cannot be used. In addition, the $GETDVI system service will only return the fully specified name, including the HSZ allocation class, for these devices.

6.6 Fibre Channel Multipath Configurations

Figure 6–16 shows a multipath configuration with the storage controllers configured in multibus mode.
Figure 6–16 Single Host With Two Dual-Ported Storage Controllers and Two Buses

Note the following about this configuration:

- Host has two adapters, each attached to a different bus.
- Each port on each HSG80 storage controller is attached to a different interconnect.
- Both storage controllers can access the same disk.
- Host has four paths to the same logical unit.

Note that each HSG80 port has its own Fibre Channel address and Fibre Channel port WWID. This is different from an HSZ80 in multibus mode where all the ports respond to the same SCSI address and must, therefore, be connected to different SCSI buses. The separate FC addresses enable both ports of the dual HSG80 to be on the same FC.

Figure 6–17 shows another multipath configuration with its storage controllers configured in multibus mode.
6.6 Fibre Channel Multipath Configurations

Figure 6–17 Single Host With Two Dual-Ported Storage Controllers and Four Buses

Note the following about this configuration:
- Host has four adapters, each attached to a different interconnect.
- Each port on each HSG80 storage controller is attached to a different interconnect.
- Host has four paths to the same logical unit.

6.7 Implementing Multipath Configurations

Parallel SCSI and Fibre Channel interconnects support multipath configurations. Implementation of these configurations is similar, and the system parameters and the command for specifying paths are the same. The syntax for the path identifiers differs.

Implementing multiple paths to devices consists of the following steps:
1. Configuring a system or systems with multiple physical paths to those devices for which you want multipath support
2. Setting the HSx controller to multibus mode
3. Optionally qualifying multipath support by setting certain multipath system and console parameters, as appropriate for your configuration
4. Optionally tailoring the operation of multipath functionality, using the DCL command SET DEVICE/qualifier/PATH=path-identifier
6.7 Implementing Multipath Configurations

6.7.1 Valid Multipath Configurations

Figure 6-18 shows a valid multipath, multihost configuration.

Figure 6–18  Two Hosts With Shared Buses and Shared Storage Controllers

Note the following about this configuration:

- Each host has two adapters.
- Both hosts are connected to the same two buses.
- Both hosts share the storage.
- Each storage controller is connected to one bus only.
- The two storage controllers are connected to the same disks.

This configuration provides each host with two direct paths and one MSCP served path to each device.

Figure 6-19 shows a valid multipath configuration for systems that are not configured on the same bus.
Figure 6–19 Two Hosts With Shared, Multiported Storage Controllers

Note the following about this configuration:

- Each host has two adapters.
- Each host is connected to two buses but the hosts do not share a bus.
- Both hosts share the storage.
- Each storage controller has two connections, one to each host.
- The two storage controllers are connected to the same disks.

This configuration provides each host with two direct paths, one to each storage controller, and one MSCP served path to each device.

6.7.2 Invalid Multipath Configuration

Figure 6–20 shows an invalid multipath configuration. The configuration is invalid because, if multiple hosts in a cluster are connected to an HSZ or HSG, they must all have connections to the same controller modules (see Table 6–1). In this configuration, each host is connected to a different controller module.
6.7.3 Multipath System Parameters

Multipath support is enabled and qualified by the use of four system parameters, as described in Table 6–3. (A fifth multipath system parameter is reserved for the operating system.)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPDEV_ENABLE</td>
<td>Enables the formation of multipath sets when set to ON (1). If set to OFF (0), the formation of additional multipath sets is disabled. However, existing multipath sets remain in effect. The default is ON.</td>
</tr>
<tr>
<td>MPDEV_LCRETRIES</td>
<td>Controls the number of times the system retries direct paths to the controller that the logical unit is online to, before moving on to direct paths to the other controller, or to an MSCP served path to the device. The valid range for retries is 1 through 256. The default is 1.</td>
</tr>
<tr>
<td>MPDEV_POLLER</td>
<td>Enables polling of the paths to multipath set members when set to ON (1). Polling allows early detection of errors on inactive paths. If a path becomes unavailable or returns to service, the system manager is notified with an OPCOM message. If set to OFF (0), multipath polling is disabled. The default is ON.</td>
</tr>
</tbody>
</table>

(continued on next page)
Table 6–3 (Cont.) Multipath System Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPDEV_REMOTE</td>
<td>Enables MSCP served disks to become members of a multipath set when set to ON (1). If set to OFF (0), only local paths to a SCSI or Fibre Channel device will be used in the formation of additional multipath sets. However, setting this parameter to OFF will not have any effect on existing multipath sets that have remote paths. This parameter must remain set to the default value of OFF. This restriction will be removed in a future release of OpenVMS.</td>
</tr>
<tr>
<td>MPDEV_D1</td>
<td>Reserved for use by the operating system.</td>
</tr>
</tbody>
</table>

If a node has MPDEV_ENABLE or MPDEV_REMOTE set to OFF, and the node has one or more direct paths and served paths to its system disk, then the node must only boot on the direct paths.

6.7.4 Path Identifiers

The system management commands described in the following sections allow you to monitor and control the operation of multipath failover. These commands provide a path identifier to uniquely specify each path in a multipath set.

Direct Fibre Channel paths are identified by the local host adapter name and the remote Fibre Channel port WWID — that is, the initiator and the target. For example, in Figure 6–21, the path identifier for the path from the host adapter on the left to the HSG storage controller on the left is PGB0.5000-1FE1-0000-0200. (The second port on each HSG is omitted for convenience.) You can obtain the WWID for a storage controller from its console.

**Figure 6–21 Fibre Channel Path Naming**

![Fibre Channel Path Naming](image)

Direct parallel SCSI paths are identified by the local host adapter name and the remote SCSI bus ID — that is, the initiator and the target. For example, in Figure 6–22, the path identifiers for node Edgar’s two direct paths to the disk would be named PKB0.5 and PKC0.5.
The path identifier for MSCP served paths is MSCP.

**Figure 6–22 Configuration With Multiple Direct Paths**

![Diagram showing configuration with multiple direct paths]

### 6.7.5 Displaying Paths

When multipath support is enabled, you can display the multiple paths to a device using either of the following variants of the SHOW DEVICE DCL command:

- `SHOW DEVICE/FULL device-name`
- `SHOW DEVICE/MULTIPATH_SET device-name`

The `SHOW DEVICE/FULL device-name` command displays the traditional information about the device first and then lists all the paths to a device by their path identifiers (described in Section 6.7.4).

The `SHOW DEVICE/MULTIPATH_SET device-name` command lists only the multiple paths to a device.

Multipath information is displayed only on nodes that are directly connected to the multipath device.

#### 6.7.5.1 Displaying Paths With SHOW DEVICE/FULL

The following example shows the output of a `SHOW DEVICE/FULL device-name` command. Note that the use of multiple paths is shown at the beginning of the display (device has multiple I/O paths), and the multiple path descriptions are shown toward the end of the display, beneath I/O paths to device. Note, too, that the values for Error count and Operations completed shown at the beginning of the display are the sums of the counts for each path.
$ SHOW DEVICE/FULL $70$DKA100:

Disk $70$DKA100: (FLAM10), device type DEC HS270, is online, mounted, file-oriented device, shareable, device has multiple I/O paths, served to cluster via MSCP Server, error logging is enabled.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error count</td>
<td>2 Operations completed 123471</td>

</tr>
</tbody>
</table>
6.7 Implementing Multipath Configurations

6.7.5.2 Displaying Paths With SHOW DEVICE/MULTIPATH_SET

You can obtain a brief listing of multiple paths for a specific device, for all the
devices in an allocation class, or for all devices with the DCL command:

SHOW DEVICE/MULTIPATH_SET [device-name]

The device name is optional; when omitted, all devices that have formed
multipath sets are shown. For each multipath device found, the device name,
host name, device status, error count, number of accessible paths, total number
of paths, and the current path's path identifier are displayed.

The host name displayed is the host name of the current path. For direct paths,
this will be the local system's host name. For MSCP served paths, this will be the
host name of the remote system which is serving access to the device.

The following example shows the output of a SHOW DEVICE /MULTIPATH
command.

$ SHO DEV /MULTIPATH
Device Device Error Current
Name Status Count Paths path
$70$DKA0: (FIBRE3) Online 0 3/3 PKB0.0
$70$DKA100: (FIBRE3) MountVerify 11 2/3 PKB0.1
$70$DKA200: (FIBRE3) Mounted 0 3/3 PKC0.2
$70$DKA300: (FIBRE3) Mounted 2 1/3 PKC0.3
$70$DKA400: (FIBRE3) Mounted 4 3/3 PKC0.4
$70$DKA500: (FIBRE3) Mounted 7 3/3 PKC0.5
$70$DKA1400: (FIBRE3) Mounted 0 3/3 PKC0.14
$70$DKA1500: (FIBRE3) Mounted 4 3/3 PKB0.15
$100$DKA100: (FIBRE3) Online 0 2/2 PKA0.1
$100$DKA200: (FIBRE3) Mounted 3 2/2 PKA0.2
$100$DKA300: (FIBRE3) Online wrlck 0 2/2 PKA0.3
$100$DKA400: (FIBRE3) Online wrlck 0 2/2 PKA0.4

If you choose to specify a partial device name, such as $70$DKA, the display
shows all devices with multiple paths whose names begin with $70$DKA.

6.7.6 Path Polling

When SCSI multipath support is in effect, the system periodically polls all the
I/O paths from each host adapter to each HSZ or HSG controller to determine the
status of each I/O path. If the system detects any changes to a path, it outputs a
message, similar to the following messages, to the console and to the operator’s
log:

All multipath devices on path PKB0.5 are either disabled or not reachable.

or

At least one multipath device on path PKB0.5 is enabled and reachable.

If all the devices on a path are removed, a path failure is reported. The path from
the host to the HSx controller may still function, but this cannot be determined
when there are no devices to poll.

You can turn polling on or off with the following command:

SET DEVICE device/[NO]POLL/PATH=path-identifier

Turning off polling for a path that will be out of service for a prolonged period is
useful because it can reduce system overhead.
6.7 Implementing Multipath Configurations

6.7.7 Switching Current Paths Manually

You can switch a device's current path manually using the SET DEVICE command with the /SWITCH qualifier. The most common reason for doing this is to balance the aggregate I/O load across multiple H5x controller modules and buses.

The command syntax for switching the current path is:

```
SET DEVICE device-name/SWITCH/PATH=path-identifier
```

The following command switches the path of device $2$DKA502 to an MSCP served path.

```
$ SET DEVICE $2$DKA502/SWITCH/PATH=MSCP
```

Note that this command initiates the process of switching the path and then returns to the DCL prompt immediately. A delay may occur between when the DCL prompt reappears and when the path switch is complete.

A manual path switch is accompanied by mount verification messages and by a status message indicating the result of the path switch request. This is shown in Example 6–1:

Example 6–1  Messages Resulting from Manual Path Switch

```
%%%%%%%%%%% OPCOM 17-MAR-1999 20:48:56.66
Device $1$DGA50: (FCNOD1 PGA, FCNOD2) is offline.
Mount verification is in progress.

$%
%%%%%%%%%%% OPCOM 17-MAR-1999 20:49:12.30
Mount verification has completed for device $1$DGA50: (FCNOD1 PGA, FCNOD2)

%%%%%%%%%%% OPCOM 17-MAR-1999 20:49:12.31
Multipath access to device $1$DGA50: has been manually switched from path PGB0.5000-1PE1-0000-0D13 to path PGA0.5000-1PE1-0000-0D12
```

You can check for completion of a path switch by issuing the SHOW DEVICE/FULL command, or the SHOW DEVICE/MULTIPATH command.

Note that if the path that is designated in a manual path switch fails during the switch operation, then automatic path switching takes over. This can result in a switch to a path different from the one designated in the command.

If a manual path switch causes a virtual unit to switch from one HSG80 controller to another controller, then the command can affect other nodes in the cluster. These nodes will experience a mount verification on their current path. This will cause an automatic switch to a path on the other HSG80 controller. The messages indicating this event are shown in Example 6–2:

Example 6–2  Messages Displayed When Other Nodes Detect a Path Switch

```
%%%%%%%%%%% OPCOM 17-MAR-1999 20:50:56.66
Device $1$DGA50: (FCNOD1 PGA, FCNOD2) is offline. Mount verification is in progress.

$%
%%%%%%%%%%% OPCOM 17-MAR-1999 20:51:12.30
Mount verification has completed for device $1$DGA50: (FCNOD1 PGA, FCNOD2)
```

(continued on next page)
Example 6–2 (Cont.) Messages Displayed When Other Nodes Detect a Path Switch

OPCOM 17-MAR-1999 20:51:12.31
Multipath access to device $1$DGA50: has been automatically switched from path PGB0.5000-1FE1-0000-0D13 to path PGA0.5000-1FE1-0000-0D13

6.7.8 Path Selection by OpenVMS

In a multipath configuration, the first path to a device that OpenVMS configures is chosen as the initial current path. Note that this overrides the selection of a preferred path through HSx console commands such as the following:

```
HSG> SET UNIT PREFERRED_PATH=THIS_CONTROLLER
```
or

```
HSG> SET UNIT PREFERRED_PATH=OTHER_CONTROLLER
```

For this reason, it is not recommended that the OpenVMS system manager set preferred paths at the HSx console. Instead the manual path switching commands, described in Section 6.7.7 should be used.

In case of failover, OpenVMS chooses an alternate path according to the following order of precedence:

1. The path specified by the system manager in a manual switch command
2. A direct path where failover from one HSx controller module to another is not required
3. A direct path, where HSx failover is required
4. MSCP served path

OpenVMS avoids unnecessary failover from one HSx controller module to another because:

- Failover from one HSx controller module to another causes a delay of approximately 1 to 15 seconds, depending on the amount of cached data that needs to be synchronized.
- Other nodes that share access to the device must reestablish communication using an alternate path.

6.7.9 How OpenVMS Performs Multipath Failover

When an I/O operation to a multipath disk fails and the failure suggests that a retry (on the current path or an alternate path) might succeed, then failover proceeds as follows:

1. Mount verification is invoked.
2. Mount verification attempts to communicate with the device on the current path and to validate that the volume is still correct.
3. If mount verification fails on the current path, then a new path is sought according to the following order:
   - Direct paths that do not require an HSx failover are attempted a few times to maximize their chance of selection (the number of retries is controlled by the SYSGEN parameter MPDEV_LCRETRIES).
Any direct path is attempted.

Any path, including the served path is attempted.

These steps execute in a loop, until a working path is located, or mount verification times out.

4. A successful mount verification restarts all failed I/Os and allows new ones to proceed.

6.7.10 Enabling or Disabling Paths as Path Switch Candidates

By default, all paths are candidates for path switching. You can disable or re-enable a path as a switch candidate by using the SET DEVICE command with the /[NO]ENABLE qualifier. The reasons you might want to do this include the following:

- You know a specific path is broken, or that a failover to that path will cause some members of the cluster to lose access.
- To prevent automatic switching to a selected path while it is being serviced.

Note that the current path cannot be disabled.

The command syntax for enabling a disabled path is:

$ SET DEVICE device-name/[NO]ENABLE/PATH=path-identifier

The following command enables the MSCP served path of device $2$DKA502.

$ SET DEVICE $2$DKA502/ENABLE/PATH=MSCP

The following command disables a local path of device $2$DKA502.

$ SET DEVICE $2$DKA502/ENABLE/PATH=PKC0.5

Be careful when disabling paths. Avoid creating an invalid configuration, such as the one shown in Figure 6–20.

6.7.11 Console Considerations

This section describes how to use the console with parallel SCSI multipath devices. Refer to Section 7.6 for information on using the console with FC multipath devices.

The console uses traditional, path-dependent, SCSI device names. For example, the device name format for disks is DK, followed by a letter indicating the host adapter, followed by the SCSI target ID, and the LUN.

This means that a multipath device will have multiple names, one for each host adapter it is accessible through. In the following sample output of a console show device command, the console device name is in the left column. The middle column and the right column provide additional information, specific to the device type.

Notice, for example, that the devices dkb100 and dkc100 are really two paths to the same device. The name dkb100 is for the path through adapter PKB0, and the name dkc100 is for the path through adapter PKC0. This can be determined by referring to the middle column, where the informational name includes the HSZ allocation class. The HSZ allocation class allows you to determine which console "devices" are really paths to the same HSZ device.
The console may not recognize a change in the HSZ allocation class value until after you issue a console INIT command.

The console does not automatically attempt to use an alternate path to a device if I/O fails on the current path. For many console commands, however, it is possible to specify a list of devices that the console will attempt to access in order. In a multipath configuration, you can specify a list of console device names that correspond to the multiple paths of a device. For example, a boot command, such as the following, will cause the console to attempt to boot the multipath device through the DKB100 path first, and if that fails, it will attempt to boot through the DKC100 path:

```plaintext
BOOT DKB100, DKC100
```
A major benefit of OpenVMS is its support of a wide range of interconnects and protocols for network configurations and for OpenVMS Cluster System configurations. This chapter describes OpenVMS Alpha support for Fibre Channel as a storage interconnect for single systems and as a shared storage interconnect for multihost OpenVMS Cluster systems.

The following topics are discussed:

- Overview of Fibre Channel (Section 7.1)
- Fibre Channel configuration requirements and restrictions (Section 7.2)
- Example configurations (Section 7.3)
- Fibre Channel addresses, WWIDs, and device names (Section 7.4)
- Fibre Channel tape support (Section 7.5)
- Using the AlphaServer console for configuring Fibre Channel (Section 7.6)
- Setting up an HSG for use with OpenVMS (Section 7.7)
- Creating a cluster with a shared Fibre Channel system disk (Section 7.8)
- Online reconfiguration (Section 7.9)

For information about multipath support for Fibre Channel configurations, see Chapter 6.

______________________________  Note  ____________________________

The Fibre Channel interconnect is shown generically in the figures in this chapter. It is represented as a horizontal line to which the node and storage subsystems are connected. Physically, the Fibre Channel interconnect is always radially wired from a switch, as shown in Figure 7–1.

The representation of multiple SCSI disks and SCSI buses in a storage subsystem is also simplified. The multiple disks and SCSI buses, which one or more HSGx controllers serve as a logical unit to a host, are shown in the figures as a single logical unit.

For ease of reference, the term HSG is used throughout this chapter to represent both an HSG60 and an HSG80, except where it is important to note any difference, as in Table 7–2. In those instances, HSG60 or HSG80 is used.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.1 Overview of Fibre Channel

Fibre Channel is an ANSI standard network and storage interconnect that offers many advantages over other interconnects. Its most important features are described in Table 7–1.

Table 7–1 Fibre Channel Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High-speed transmission</td>
<td>1.06 gigabits per second, full duplex, serial interconnect (can simultaneously transmit and receive 100 megabytes of data per second)</td>
</tr>
<tr>
<td>Choice of media</td>
<td>OpenVMS support for fiber-optic media.</td>
</tr>
<tr>
<td>Long interconnect distances</td>
<td>OpenVMS support for multimode fiber at 500 meters per link and for single-mode fiber up to 100 kilometers per link.</td>
</tr>
<tr>
<td>Multiple protocols</td>
<td>OpenVMS support for SCSI–3. Possible future support for IP, 802.3, HIPPI, ATM, IPI, and others.</td>
</tr>
<tr>
<td>Numerous topologies</td>
<td>OpenVMS support for switched FC (highly scalable, multiple concurrent communications) and for multiple switches. Possible future support for mixed arbitrated loop and switches.</td>
</tr>
</tbody>
</table>

Currently, the OpenVMS implementation supports:

- Single FC switch topology
- Multiple FC switches (fabric)
- Multimode fiber-optic media, at distances of up to 500 meters per link
- Single-mode fiber-optic media for interswitch links (ISLs) at distances up to 100 kilometers

Figure 7–1 shows a logical view of a switched topology. The FC nodes are either Alpha hosts, or storage subsystems. Each link from a node to the switch is a dedicated FC connection. The switch provides store-and-forward packet delivery between pairs of nodes. Concurrent communication between disjoint pairs of nodes is supported by the switch.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.1 Overview of Fibre Channel

Figure 7–1  Switched Topology (Logical View)
Figure 7–2 shows a physical view of a Fibre Channel switched topology. The configuration in Figure 7–2 is simplified for clarity. Typical configurations will have multiple Fibre Channel interconnects for high availability, as shown in Section 7.3.4.

**Figure 7–2 Switched Topology (Physical View)**

---

### 7.2 Fibre Channel Configuration Support

OpenVMS Alpha supports the Fibre Channel devices listed in Table 7–2. Note that Fibre Channel hardware names typically use the letter G to designate hardware that is specific to Fibre Channel. Fibre Channel configurations with other Fibre Channel equipment are not supported. To determine the required minimum versions of the operating system and firmware, see the release notes.
Confi guring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.2 Fibre Channel Configuration Support

Compaq recommends that all OpenVMS Fibre Channel configurations use the latest update kit for the OpenVMS version they are running:

The root name of these kits is FIBRE_SCSI, a change from the earlier naming convention of FIBRECHAN. The kits are available from the following web site:

http://www.compaq.com/support/

1 On the AlphaServer 800, the integral S3 Trio must be disabled when the KGPSA is installed.
2 Console support for FC disks is not available on this model.

OpenVMS supports the Fibre Channel SAN configurations described in the latest Compaq StorageWorks Heterogeneous Open SAN Design Reference Guide (order number: AA-RMPNA-TE) and the Data Replication Manager (DRM) user documentation. This includes support for:

- Multiswitch FC fabrics.
- Support for up to 500 meters of multimode fiber, and support for up to 100-kilometer interswitch links (ISLs) using single-mode fiber. In addition, DRM configurations provide longer-distance ISLs through the use of the Open Systems Gateway and Wave Division Multiplexors.
- Sharing of the fabric and the HSG storage with non-OpenVMS systems.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.2 Fibre Channel Configuration Support

The StorageWorks documentation is available from their web site. First locate the product; then you can access the documentation. The WWW address is:
http://www.compaq.com/storage

Within the configurations described in the StorageWorks documentation, OpenVMS provides the following capabilities and restrictions:

• All OpenVMS disk functions are supported: system disk, dump disks, shadow set member, quorum disk, and MSCP served disk. Each virtual disk must be assigned an identifier that is unique clusterwide.

• OpenVMS provides support for the number of hosts, switches, and storage controllers specified in the StorageWorks documentation. In general, the number of hosts and storage controllers is limited only by the number of available fabric connections.

• The number of Fibre Channel host bus adapters per platform depends on the platform type. Currently, the largest platforms support up to 26 adapters (independent of the number of OpenVMS instances running on the platform).

• OpenVMS requires that the HSG operate in SCSI-3 mode, and if the HSG is in a dual redundant configuration, then the HSG must be in multibus failover mode. The HSG can only be shared with other systems that operate in these modes.

• The OpenVMS Fibre Channel host bus adapter must be connected directly to the FC switch. The host bus adapter is not supported on a Fibre Channel loop, nor in a point-to-point connection to another Fibre Channel end node. Other ports on the Fibre Channel switch can be connected to Fibre Channel loops or to QuickLoops. (The Compaq StorageWorks SAN Switch QuickLoop is a Fibre Channel topology that combines the services of fabric and Fibre Channel Arbitrated Loop (FC-AL) management.)

• Neither the KGPSA-BC nor the KGPSA-CA can be connected to the same PCI bus as the S3 Trio 64V+ Video Card (PB2GA-J C/JD). On the AlphaServer 800, the integral S3 Trio must be disabled when the KGPSA is installed.

• Hosts on the fabric can be configured as a single cluster or as multiple clusters and/or nondistributed nodes. It is critical to ensure that each cluster and each non-clustered system has exclusive access to its storage devices. HSG access IDs and/or FC switch zoning can be used to ensure that each HSG storage device is accessible to only one cluster or one non-clustered system.

• The HSG supports a limited number of connections. A connection is a non-volatile record of a particular host bus adapter communicating with a particular port on the HSG. (Refer to the HSG CLI command SHOW CONNECTIONS.) The HSG ACS V8.5 allows a maximum of 64 connections and ACS V8.4 allows a maximum of 32 connections. The connection limit is the same for both single and dual redundant controllers.

If your FC fabric is large, and the number of active connections exceeds the HSG limit, then you must reconfigure the fabric, or use FC switch zoning to "hide" some of the adapters from some of the HSG ports, in order to reduce the number of connections.
The HSG does not delete connection information from the connection table when a host bus adapter is disconnected. Instead, the user must prevent the table from becoming full by explicitly deleting the connection information using a CLI command.

This configuration support is in effect as of the revision date of this document. OpenVMS plans to increase these limits in future releases.

In addition to the configurations already described, OpenVMS also supports the SANworks Data Replication Manager. This is a remote data vaulting solution that enables the use of Fibre Channel over longer distances. For more information, see the Compaq StorageWorks web site at:

http://www.compaq.com/products/storageworks

7.2.1 Fibre Channel Remedial Kits

Qualification of new Fibre Channel hardware and larger configurations is ongoing. New hardware and larger configurations may necessitate enhancements to the Fibre Channel support in OpenVMS. Between releases of OpenVMS, enhancements and corrections to Fibre Channel software are made available by means of remedial kits. Compaq recommends that you monitor the Fibre Channel web site (http://www.openvms.compaq.com/openvms/fibre/) and the Compaq support web site (http://www.compaq.com/support/) for updates for the operating system version you are running.

The latest version of each kit is always posted to the Compaq support web site.

7.2.2 Mixed-Version and Mixed-Architecture Cluster Support

Shared Fibre Channel OpenVMS Cluster storage is supported in both mixed-version and mixed-architecture OpenVMS Cluster systems. The following configuration requirements must be observed:

- All hosts configured for shared access to the same storage devices must be in the same OpenVMS Cluster.
- All hosts in the cluster require a common cluster communication interconnect, such as a LAN, CI, or DSSI.
- All hosts with a direct connection to the FC must be running one of the following versions of OpenVMS Alpha:
  7.3
  7.2-1H1
  7.2-1
  7.2 with the DEC-AXPVMS-VMS72_HARDWARE-V0100-4.PCSI remedial kit and console revision 5.4 or higher, depending on the AlphaServer model (see the release notes)
- All hosts that receive MSCP service of FC disks must have one of the following update kits (or later) installed:
  - Alpha systems
    + Version 6.2: ALPDRIV20_062
    + Version 7.1: ALPDRIV11_071
    + Version 7.1-2: DEC-AXPVMS-VMS712_DRIVER-V0300-4.PCSI
  - VAX systems
    + Version 6.2: VAXDRIV07_062
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.2 Fibre Channel Configuration Support

+ Version 7.1: VAXDRIV05_071
+ Version 7.2: VAXDRIV01_072

- DECevent Version 2.9 or later must be used for error tracing. Earlier versions of DECevent do not support Fibre Channel.

7.2.3 Fibre Channel and Volume Shadowing for OpenVMS

Since Fibre Channel support was introduced in OpenVMS Alpha, shadowing of directly connected Fibre Channel storage using Volume Shadowing for OpenVMS, has been available. OpenVMS Alpha Version 7.2-1 extended this support to the shadowing of Fibre Channel multipath devices.

7.2.4 Fibre Channel and OpenVMS Galaxy Configurations

Fibre Channel is supported in all OpenVMS Galaxy configurations. For more information about Galaxy configurations, see the OpenVMS Alpha Partitioning and Galaxy Guide.

7.3 Example Configurations

This section presents example Fibre Channel configurations. The configurations build on each other, starting with the smallest valid configuration and adding redundant components for increasing levels of availability, performance, and scalability.

7.3.1 Single Host with Dual-Ported Storage

Figure 7–3 shows a single system using Fibre Channel as a storage interconnect.

Figure 7–3 Single Host With One Dual-Ported Storage Controller

Note the following about this configuration:

- Dual ports of the HSG storage controller increase the availability and performance of the storage subsystem.
- Extra ports on the switch enable system growth.
- To maximize performance, logical units can be spread over the two HSG ports.
• The switch and the HSG are single points of failure. To provide higher availability, Volume Shadowing for OpenVMS can be used to replicate the data to another Fibre Channel switch and HSG controller.

7.3.2 Multiple Hosts With One Dual-Ported Storage Controller

Figure 7–4 shows multiple hosts connected to a dual-ported storage subsystem.

Note the following about this configuration:
• Multiple hosts increase availability of the entire system.
• Extra ports on the switch enable system growth.
• The switch and the HSG are single points of failure. To provide higher availability, Volume Shadowing for OpenVMS can be used to replicate the data to another Fibre Channel switch and HSG controller.
7.3.3 Multiple Hosts With Storage Controller Redundancy

Figure 7–5 shows multiple hosts connected to two dual-ported storage controllers.

This configuration offers the following advantages:

• Logical units can be spread over the four HSG ports, offering higher performance.
• HSGs can be configured in multibus failover mode, even though there is just one Fibre Channel “bus.”
• The switch is still a single point of failure. To provide higher availability, Volume Shadowing for OpenVMS can be used to replicate the data to another Fibre Channel switch and HSG controller.
7.3.4 Multiple Hosts With Multiple Independent Switches

Figure 7–6 shows multiple hosts connected to two switches, each of which is connected to a pair of dual-ported storage controllers.

This two-switch configuration offers the advantages of the previous configurations plus the following:

• Higher level of availability afforded by two switches. There is no single point of failure.
• Better performance because of the additional host bus adapter.
• Each host has multiple independent paths to a storage subsystem. The two switches are not connected to each other to ensure that the paths are completely independent.
7.3.5 Multiple Hosts With Dual Fabrics

Figure 7–7 shows multiple hosts connected to two fabrics; each fabric consists of two switches.

Figure 7–7 Multiple Hosts With Dual Fabrics

This dual-fabric configuration offers the advantages of the previous configurations plus the following advantages:

- More ports are available per fabric for connecting to additional hosts and storage subsystems.
- Each host has four host bus adapters, one for each switch. Only two adapters are required, one per fabric. The additional adapters increase availability and performance.
7.3.6 Multiple Hosts With Larger Fabrics

The configurations shown in this section offer even higher levels of performance and scalability.

Figure 7–8 shows multiple hosts connected to two fabrics. Each fabric has four switches.

Figure 7–8 Multiple Hosts With Larger Dual Fabrics
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.3 Example Configurations

Figure 7-9 shows multiple hosts connected to four fabrics. Each fabric has four switches.

Figure 7–9 Multiple Hosts With Four Fabrics

7.4 Fibre Channel Addresses, WWIDs, and Device Names

Fibre Channel devices for disk and tape storage come with factory-assigned worldwide IDs (WWIDs). These WWIDs are used by the system for automatic FC address assignment. The FC WWIDs and addresses also provide the means for the system manager to identify and locate devices in the FC configuration. The FC WWIDs and addresses are displayed, for example, by the Alpha console and by the HSG console. It is necessary, therefore, for the system manager to understand the meaning of these identifiers and how they relate to OpenVMS device names.

7.4.1 Fibre Channel Addresses and WWIDs

In most situations, Fibre Channel devices are configured to have temporary addresses. The device's address is assigned automatically each time the interconnect initializes. The device may receive a new address each time a Fibre Channel is reconfigured and reinitialized. This is done so that Fibre Channel devices do not require the use of address jumpers. There is one Fibre Channel address per port, as shown in Figure 7-10.
Confi guring Fibre Channel as an OpenVMS Cluster Storage Interconnect

7.4 Fibre Channel Addresses, WWIDs, and Device Names

Figure 7–10 Fibre Channel Host and Port Addresses

In order to provide more permanent identification, each port on each device has a WWID, which is assigned at the factory. Every Fibre Channel WWID is unique. Fibre Channel also has node WWIDs to identify multiported devices. WWIDs are used by the system to detect and recover from automatic address changes. They are useful to system managers for identifying and locating physical devices.

Figure 7–11 shows Fibre Channel components with their factory-assigned WWIDs and their Fibre Channel addresses.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.4 Fibre Channel Addresses, WWIDs, and Device Names

Figure 7–11 Fibre Channel Host and Port WWIDs and Addresses

Note the following about this figure:
• Node name and port name of the host adapter are identical. (This is true in the current implementation.)
• Host adapter’s port and node name is a 64-bit, factory-assigned WWID.
• Host adapter’s address is a 24-bit automatic, transient assignment.
• Each HSG storage port has a 64-bit, factory-assigned WWID, and a 24-bit transient address that is automatically assigned.
• HSG controller pair share a node name that is a 64-bit, factory-assigned WWID.

7.4.2 OpenVMS Names for Fibre Channel Devices

There is an OpenVMS name for each Fibre Channel storage adapter, for each path from the storage adapter to the storage subsystem, and for each storage device. These sections apply to both disk devices and tape devices, except for Section 7.4.2.3, which is specific to disk devices. Tape device names are described in Section 7.5.

7.4.2.1 Fibre Channel Storage Adapter Names

Fibre Channel storage adapter names, which are automatically assigned by OpenVMS, take the form FGx0:
• FG represents Fibre Channel.
• x represents the unit letter, from A to Z.
• 0 is a constant.
The naming design places a limit of 26 adapters per system. This naming may be modified in future releases to support a larger number of adapters.

Fibre Channel adapters can run multiple protocols, such as SCSI and LAN. Each protocol is a pseudodevice associated with the adapter. For the initial implementation, just the SCSI protocol is supported. The SCSI pseudodevice name is \texttt{PG}x0, where \(x\) represents the same unit letter as the associated \texttt{FG}x0 adapter.

These names are illustrated in Figure 7–12.

**Figure 7–12  Fibre Channel Initiator and Target Names**

**7.4.2.2 Fibre Channel Path Names**

With the introduction of multipath SCSI support, as described in Chapter 6, it is necessary to identify specific paths from the host to the storage subsystem. This is done by concatenating the SCSI pseudodevice name, a decimal point (.), and the WWID of the storage subsystem port that is being accessed. For example, the Fibre Channel path shown in Figure 7–12 is named PGB0.4000-1FE1-0000-0D04.

Refer to Chapter 6 for more information on the display and use of the Fibre Channel path name.

**7.4.2.3 Fibre Channel Disk Device Identification**

The four identifiers associated with each FC disk device are shown in Figure 7–13.
The logical unit number (LUN) is used by the system as the address of a specific device within the storage subsystem. This number is set and displayed from the HSG console by the system manager. It can also be displayed by the OpenVMS SDA utility.

Each Fibre Channel disk device also has a WWID to provide permanent, unique identification of the device. The HSG device WWID is 128 bits. Half of this identifier is the WWID of the HSG that created the logical storage device, and the other half is specific to the logical device. The device WWID is displayed by the HSG console and the AlphaServer console.

The third identifier associated with the storage device is a user-assigned device identifier. A device identifier has the following attributes:

- User assigned at the HSG console.
- User must ensure it is cluster unique.
- Moves with the device.
- Can be any decimal number from 0 to 32766, except for MSCP served devices.

If the FC disk device is MSCP served, the device identifier is limited to 9999. This restriction will be removed in a future release.

The device identifier has a value of 567 in Figure 7–13. This value is used by OpenVMS to form the device name so it must be unique throughout the cluster. (It may be convenient to set the device identifier to the same value as the logical unit number (LUN). This is permitted as long as the device identifier is unique throughout the cluster.)

A Fibre Channel storage device name is formed by the operating system from the constant $1$DGA and a device identifier, $nnnn$. The only variable part of the name is its device identifier, which you assign at the HSG console. Figure 7–13 shows a storage device that is known to the host as $1$DGA567.
7.5 Fibre Channel Tape Support (Alpha)

This section describes the configuration requirements and user commands necessary to utilize the Fibre Channel tape functionality. Fibre Channel tape functionality refers to the support of SCSI tapes and SCSI tape libraries in an OpenVMS Cluster system with shared Fibre Channel storage. The SCSI tapes and libraries are connected to the Fibre Channel by a Fibre-to-SCSI bridge known as the Modular Data Router (MDR).

7.5.1 Minimum Hardware Configuration

Following is the minimum Fibre Channel tape hardware configuration:

- Alpha system with KGPSA adapter
- Compaq Modular Data Router (MDR), minimum firmware revision 1170
- Fibre Channel Switch
- Tape library, for example:
  - ESL9000 series
  - TL891
  - TL895
- Individual tapes, for example:
  - TZ89
  - DLT8000

Note

The MDR must be connected to a switch and not directly to an Alpha system.

The MDR must be in SCSI Command Controller (SCC) mode, which is normally the default. If the MDR is not in SCC mode, use the command SetSCCmode On at the MDR console.

Tapes are not supported in an HSGxx storage subsystem nor behind an FCTC-II (Fibre Channel Tape Controller II).

Tape devices and tape library robots must not be set to SCSI target ID 7, since that ID is reserved for use by the MDR. A tape library robot is an example of a medium changer device, the term that is used throughout this section.

7.5.2 Overview of Fibre Channel Tape Device Naming

This section provides detailed background information about Fibre Channel Tape device naming.

Tape and medium changer devices are automatically named and configured using the SYSMAN IO FIND and IO AUTOCONFIGURE commands described in Section 7.5.3. System managers who configure tapes on Fibre Channel should refer directly to this section for the tape configuration procedure.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.5 Fibre Channel Tape Support (Alpha)

7.5.2.1 Tape and Medium Changer Device Names

Fibre Channel tapes and medium changers are named using a scheme similar to Fibre Channel disk naming.

On parallel SCSI, the device name of a directly attached tape implies the physical location of the device; for example, MKB301 resides on bus B, SCSI target ID 3, and LUN 1. Such a naming scheme does not scale well for Fibre Channel configurations, in which the number of targets or nodes can be very large.

Fibre Channel tape names are in the form $2MGAN$. The letter for the controller is always A, and the prefix is $2$. The device mnemonic is MG for tapes and GG for medium changers. The device unit n is automatically generated by OpenVMS.

The name creation algorithm chooses the first free unit number, starting with zero. The first tape discovered on the Fibre Channel is named $2MGA0$, the next is named $2MGA1$, and so forth. Similarly, the first medium changer detected on the Fibre Channel is named $2GGA0$. The naming of tapes and medium changers on parallel SCSI buses remains the same.

Note the use of allocation class 2. Allocation class 1 is already used by devices whose name is keyed by a user-defined identifier (UDID), as with HSG Fibre Channel disks ($1DGANnnn$) and HSG Console command LUNs ($1GGANnnn$).

An allocation class of 2 is used by devices whose names are obtained from the file, SYS$DEVICES.DAT. The names are based on a worldwide identifier (WWID) key, as described in the following sections. Also note that, while GG is the same mnemonic used for both medium changers and HSG Command Console LUNs (CCLs), medium changers always have an allocation class of 2 and HSG CCLs an allocation class of 1.

Tape and medium changer names are automatically kept consistent within a single OpenVMS Cluster system. Once a tape device is named by any node in the cluster, all other nodes in the cluster automatically choose the same name for that device, even if this overrides the first free unit number algorithm. The chosen device name remains the same through all subsequent reboot operations in the cluster.

If multiple nonclustered Alpha systems exist on a SAN and need to access the same tape device on the Fibre Channel, then the upper-level application must provide consistent naming and synchronized access.

7.5.2.2 Use of Worldwide Identifiers (WWIDs)

For each Fibre Channel tape device name, OpenVMS must uniquely identify the physical device that is associated with that name.

In parallel SCSI, directly attached devices are uniquely identified by their physical path (port/target/LUN). Fibre Channel disks are uniquely identified by user-defined identifiers (UDIDs). These strategies are either unscalable or unavailable for Fibre Channel tapes and medium changers.

Therefore, the identifier for a given Fibre Channel tape or medium changer device is its worldwide identifier (WWID). The WWID resides in the device firmware and is required to be unique by the Fibre Channel standards.

WWIDs can take several forms, for example:

- IEEE registered WWID (64-bit binary)
- Vendor ID plus product ID plus serial number (ASCII)
The overall WWID consists of the WWID data prefixed by a binary WWID header, which is a longword describing the length and type of WWID data.

In general, if a device reports an IEEE WWID, OpenVMS chooses this as the unique identifying WWID for the device. If the device does not report such a WWID, then the ASCII WWID is used. If the device reports neither an IEEE WWID nor serial number information, then OpenVMS does not configure the device. During the device discovery process, OpenVMS rejects the device with the following message:

%SYSMAN-E-NOWWID, error for device Product-ID, no valid WWID found.

The WWID structures can be a mix of binary and ASCII data. These formats are displayable and are intended to be consistent with those defined by the console WWIDMGR utility. Refer to the WWIDMGR User's Manual for additional information. Note that if the data following the WWID header is pure ASCII data, it must be enclosed in double quotation marks.

The displayable format of a 64-bit IEEE WWID consists of an 8-digit hexadecimal number in ASCII (the WWID header), followed by a colon (:) and then the IEEE WWID data. For example:

0C000008:0800-4606-8010-CD3C

The displayable format of an ASCII WWID consists of an 8-digit WWID header, followed by a colon (:) and then the concatenation of the 8-byte vendor ID plus the 16-byte product ID plus the serial number. For example:

04100022:"COMPAQ DLT8000 JF71209240"

Note
Occasionally, an ASCII WWID may contain nonprintable characters in the serial number. In a displayable format, such a character is represented by \nn, where \n is the 2-digit ASCII hexadecimal value of the character. For example, a null is represented by \00.

7.5.2.3 File-Based Device Naming

Fibre Channel tape and medium changer devices are configured according to information found in the SYSSYSTEM:SYSS$DEVICES.DAT file. This is an ASCII file consisting of two consecutive records per device, where the two records are in the following form:

[Device $2$devnam]
WWID = displayable_identifier

During autoconfiguration, the Fibre Channel is probed and the WWIDs are fetched for all devices. If the fetched WWID matches an entry in the memory-resident copy of the SYSS$DEVICES.DAT file, then the device is configured using the device name that has been paired with that WWID.
Note

The SYS$DEVICES.DAT file is also used for port allocation class (PAC) information. In OpenVMS Alpha Version 7.3, Fibre Channel tape-naming becomes a second use of this same file, even though PACs and Fibre Channel tapes are not related, other than their common need to access file-based device information at boot time.

By default, the SYS$DEVICES.DAT file is created in the cluster common directory, SYS$COMMON:[SYSEXE].

As an example, the following portion of SYS$DEVICES.DAT causes the eventual configuration of devices named $2$MGA300 and $2$MGA23:

```
! [Device $2$MGA300]
WWID = 04100022:"COMPAQ DLT8000 JF71209240"
!
[Device $2$mga23]
WWID = 04100022:"DEC TZ89 (C) DECJL01164302"
```

Although the file is typically read and written only by OpenVMS utilities, in rare instances you may need to edit the file. In OpenVMS Alpha Version 7.3, you can change only the unit number of the device, as described in Section 7.5.5. The internal syntax rules governing the file are summarized as follows:

- Comment lines (beginning with !) and blank lines are permitted.
- Any white space (or none) can separate [Device from the device name represented by $2$xxx].
- Failure to supply the $2$ prefix will result in a console warning.

Similarly, on the line containing WWID = , any white space (or none) can appear on either side of the equals sign. All lines must be left-justified, and all lines must be less than 512 characters.

The parsing of this file is not case sensitive, with one important exception: all characters enclosed within double quotation marks are taken literally, so that characters such as spaces and lowercase letters are significant. In the case of ASCII data enclosed by double quotation marks, there must be no space between the colon and the double quotation mark.

Also, if more than one WWID = line follows a single [Device devnam] line, the last WWID = value takes precedence. Normally, however, there is exactly one WWID = line per [Device devnam] line.

Similarly, if two or more [Device devnam] lines specify the same device name but different WWIDs, only the last device name and WWID specified in the file is used.

This file is read at boot time, and it is also read from and written to by the SYSMAN IO FIND_WWID command. If there are additional system-specific copies of the SYS$DEVICES.DAT file, their tape naming records become automatically compatible as a result of running SYSMAN IO FIND_WWID on each system. The SYSMAN IO FIND_WWID command is described in more detail in the following section.
7.5.3 New Commands and Features for Fibre Channel Tape Devices

Two new System Management utility (SYSMAN) commands have been added. They are:

- **IO FIND_WWID**
  Probes all ports on the Fibre Channel and detects all previously undiscovered tapes and medium changers, and assigns a name to each. Displays a list of the devices and their assigned device names, and automatically records this information in the SYS$SYSTEM:SYS$DEVICES.DAT file. Also updates relevant local and clusterwide memory structures.
  Use this command prior to running the SYSMAN command IO AUTOCONFIGURE.
  Requires the CMKRNL privilege.

- **IO REPLACE_WWID**
  Updates appropriate file and memory data structures in case one tape drive must be physically replaced by another tape drive at the same FC LUN location.
  Requires the CMKRNL privilege.

The following DCL enhancements have been made:

- The SHOW DEVICE/FULL command now displays the WWID for Fibre Channel tape devices.
- The F$GETDVI lexical function now supports the new keyword WWID, which returns the Fibre Channel tape device's WWID.

7.5.4 Configuring a Fibre Channel Tape Device

This section lists the steps required to configure a new tape or medium changer on the Fibre Channel.

7.5.4.1 Basic Configuration Steps: Summary

The basic steps for configuring new Fibre Channel tape devices in a cluster are as follows:

1. Power on the new tape device(s).
2. Powercycle the MDR to update MDR mapping information.
3. Run SYSMAN to assign device names and configure the devices:

```sh
$ MC SYSMAN
SYSMAN> SET ENVIRONMENT/CLUSTER ! Execute on all nodes
SYSMAN> IO FIND_WWID ! Assign names
SYSMAN> IO AUTOCONFIGURE/LOG ! Configure devices
SYSMAN> EXIT
```

You need to perform these steps only once for the initial configuration. After any subsequent system reboot, the devices will appear automatically.
Prior to configuring a tape device on Fibre Channel, the worldwide identifier (WWID) of the device must be detected and stored, along with a device name, in the text file SYS$SYSTEM:SYS$DEVICES.DAT. This is accomplished by using the new SYSMAN command IO FIND_WWID.

The IO FIND_WWID command probes all ports on the Fibre Channel and locates all tape and medium changer devices connected to an MDR. For tapes and medium changers that have not been detected by a previous IO FIND_WWID command, IO FIND_WWID assigns a device name, retrieves the WWID of the device, stores the device name and WWID data in the SYS$SYSTEM:SYS$DEVICES.DAT file, and updates memory structures.

Since the primary goal of IO FIND_WWID is to populate the SYS$DEVICES.DAT file, you need to invoke the IO FIND_WWID command only once for each device. IO FIND_WWID does not configure the $2$MGA$nnnn$ device for use by an application.

Once the information is stored in the file, subsequent use of the IO AUTOCONFIGURE command reads a memory-resident copy of the file and configures the tape and medium changer devices automatically, loading or connecting the device drivers as needed. The SYS$DEVICES.DAT file is read into memory during each system reboot; this action initiates the automatic configuration of tapes and medium changers on the Fibre Channel.

Note that running the IO FIND_WWID command for the first time detects all existing tape and medium changer devices on the system. If you add additional Fibre Channel tape devices to the system at a later time, you must first powercycle the MDR to update internal mapping information, and then run the IO FIND_WWID command again to append the new device information to the SYS$DEVICES.DAT file.

In an OpenVMS Cluster environment, various data structures in memory must be updated on each system when a new Fibre Channel tape device is added. To accomplish this, Compaq recommends that you run the SYSMAN IO FIND_WWID command on each Alpha node in the cluster. Alternatively, you can run IO FIND_WWID on one node, and then reboot the other nodes that share that same system disk, because the SYS$DEVICES.DAT file is read at boot time and causes memory structures to be correctly initialized.

In the case of multiple system disks in the cluster, ensure that all copies of the SYS$DEVICES.DAT file are kept consistent, preferably by running the IO FIND_WWID command on all nodes. Alternatively, you can run IO FIND_WWID to update just one SYS$DEVICES.DAT file, and then manually edit the remaining SYS$DEVICES.DAT files by cutting and pasting the appropriate device name and WWID records from the original file to the target files.

Compaq recommends that you refrain from copying the entire original file to another system disk. The SYS$DEVICES.DAT file is also used to define port allocation classes (PACs), and PAC entries could be transferred inadvertently to the target system.

Following is a configuration example using a TL891 tape library on a single node.

First, the SYSMAN command IO FIND_WWID displays a list of all previously undiscovered tape devices and their device names.
Confiuiguring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.5 Fibre Channel Tape Support (Alpha)

$ MCR SYSMAN IO FIND_WWID
%SYSMAN-I-OUTPUT, command execution on node SAMPLE
On port _SAMPLE$PGA0:, the following tape WWIDs and their proposed device names have been found but not yet configured:

[Device $2$GGA0]
WWID=04100024:"DEC TL800 (C) DEC3G9CCR82A017"

[Device $2$MGA0]
WWID=04100022:"DEC T289 (C) DECCX939S2777"

[Device $2$MGA1]
WWID=04100022:"DEC T289 (C) DECCX942S6295"

Note that the overall WWID consists of everything to the right of the equals sign. Each such WWID is unique; however, the header portion may not be unique, because the header reflects only the basic type and length of the WWID data.

The IO FIND_WWID command automatically records the information about the new tape devices in SYS$SYSTEM:SYS$DEVICES.DAT:

$ TYPE SYS$SYSTEM:SYS$DEVICES.DAT

[Device $2$GGA0]
WWID=04100024:"DEC TL800 (C) DEC3G9CCR82A017"

! Updated 23-OCT-2000 14:17:41.93: DEC T289

[Device $2$MGA0]
WWID=04100022:"DEC T289 (C) DECCX939S2777"

! Updated 23-OCT-2000 14:17:42.01: DEC T289

[Device $2$MGA1]
WWID=04100022:"DEC T289 (C) DECCX942S6295"

Next, the SYSMAN command IO AUTOCONFIGURE configures the tape device.

$ MCR SYSMAN IO AUTOCONFIGURE/LOG
%SYSMAN-I-OUTPUT, command execution on node SAMPLE
%IOGEN-I-PREFIX, searching for ICBM with prefix SYS$
%IOGEN-I-PREFIX, searching for ICBM with prefix DECW$
%IOGEN-I-SCSIPOLL, scanning for devices through SCSI port PKA0
%IOGEN-I-SCSIPOLL, scanning for devices through SCSI port PKB0
%IOGEN-I-FIBREPOL, scanning for devices through FIBRE port PFA0
%IOGEN-I-CONFIGURED, configured device GGA0
%IOGEN-I-CONFIGURED, configured device MGA0
%IOGEN-I-CONFIGURED, configured device MGA1

Finally, the SHOW DEVICE/FULL command displays the WWID of the tape device.

$ SHOW DEVICE/FULL $2$MG

Magtape $2$MGA0: (SAMPLE), device type T289, is online, file-oriented device, available to cluster, error logging is enabled, controller supports compaction (compaction disabled), device supports fastskip.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.5 Fibre Channel Tape Support (Alpha)

Error count 0 Operations completed 0
Owner process " " Owner UIC [SYSTEM]
Owner process ID 00000000 Dev Prot S:RWPL,O:RWPL,G:R,W
Reference count 0 Default buffer size 2048
WWID 04100022: "DEC T289 (C) DECCX939S2777"
Density default Format Normal-11
Allocation class 2

Volume status: no-unload on dismount, position lost, odd parity.

Magtape $2$MGA1: (SAMPLE), device type T289, is online, file-oriented device, available to cluster, error logging is enabled, controller supports compaction (compaction disabled), device supports fastskip.

Error count 0 Operations completed 0
Owner process " " Owner UIC [SYSTEM]
Owner process ID 00000000 Dev Prot S:RWPL,O:RWPL,G:R,W
Reference count 0 Default buffer size 2048
WWID 04100022: "DEC T289 (C) DECCX942S6295"
Density default Format Normal-11
Allocation class 2

Volume status: no-unload on dismount, position lost, odd parity.

The F$GETDVI lexical function also retrieves the displayable WWID:

$ write sys$output f$getdvi("$2$MGA0","WWID")
04100022: "DEC T289 (C) DECCX939S2777"

Once the device is named and configured, you can use the device in the same way that you use parallel SCSI tapes with DCL commands such as INITIALIZE, MOUNT, BACKUP, and COPY. Refer to the installation guide for individual tape layered products for details on product-specific support of Fibre Channel tapes.

Note that while medium changers on Fibre Channel are autoconfigured, the medium changers on parallel SCSI continue to require the IO CONNECT command to load the device driver. It is impossible to manually connect a Fibre Channel medium changer by the SYSMAN IO CONNECT command because the device name does not imply the device's physical location, as it does in parallel SCSI.

7.5.5 Changing the Name of an Existing Fibre Channel Tape Device

Because SYS$SYSTEM:SYS$DEVICES.DAT is a text file, you can edit it but only to change the unit number of a Fibre Channel tape or medium changer device. However, as stated earlier, Fibre Channel tape and medium changer device information is stored internally by OpenVMS using clusterwide data structures, specifically clusterwide logical names. In OpenVMS Version 7.3, the only supported way to clean up these data structures is to do a complete cluster shutdown. A rolling reboot (leaving at least one node up during the reboot of other nodes) is inadequate to clean up the structures.

The specific steps for changing an existing device name follow:

1. Edit the SYS$SYSTEM:SYS$DEVICES.DAT file to change the unit number of the chosen device. In the basic $2$MGAaaaa or $2$GGAaaaa format, only the aaaa portion can be edited. The maximum allowed value for aaaa is 9999 and must be decimal. Be sure to choose a unit number that is not already in use by another device for that device type.

For example, if $2$MGA26 is already associated with the WWID of another tape, then choose a unit number other than 26; if $2$GGA4 is already associated with the WWID of another medium changer, then choose a unit number other than 4.
2. If there are multiple system disks in the cluster, edit each of the SYS$DEVICES.DAT files in the same way.

3. Shut down the entire cluster to clean up existing cluster data structures.

4. Reboot the cluster. The new device names will automatically appear.

7.5.6 Moving a Physical Tape Device on Fibre Channel

To move a tape or medium changer device without changing its name, a cluster shutdown is not required. However, you must reboot each cluster node that will access the device so that the path information is updated in the unit control blocks that represent the device.

<table>
<thead>
<tr>
<th>Caution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use of the MDR commands RemapFcScsi or ClearFcScsiMap will result in a remapping of Fibre Channel paths inside the MDR. As a result, the devices will appear to have been moved even though no physical action was taken. For consistency, you should avoid using these commands on an already configured system.</td>
</tr>
</tbody>
</table>

If a device is inadvertently moved to a new path without rebooting, then subsequent attempts to mount or initialize the device, or to issue a "$QIO IO$PACKACK to it will fail with a fatal drive error.

7.5.7 Serving a Fibre Channel Tape Device

In general, all OpenVMS Alpha Version 7.3 nodes in an OpenVMS Cluster have a direct path to Fibre Channel tape devices if the nodes are connected to the same Fibre Channel fabric as the MDR. VAX nodes and Alpha nodes running earlier versions of OpenVMS, as TMSCP clients, can be served Fibre Channel tape devices by an OpenVMS Alpha Version 7.3 node. To provide this feature, pre-Version 7.3 VAX nodes require the latest update kit for TUDRIVER.EXE, and pre-Version 7.3 Alpha nodes require the latest update kit for SYS$TUDRIVER.EXE.

Medium changers, whether connected to Fibre Channel or to parallel SCSI, cannot be TMSCP served.

7.5.8 Replacing a Fibre Channel Tape Device

If one tape drive must be physically replaced by another tape drive at the same FC LUN location within the MDR, update the appropriate data structures with the IO REPLACE_WWID command.

For example, you may need to replace a defective tape drive with a new drive without rebooting the cluster, and that drive may need to retain the device name of the previous tape at that location.

The replacement device should have the same SCSI target ID as the original device. Cease all activity on the device, then type the following command to update all the necessary file and memory data structures with the WWID of the new tape drive:

```
$ MCR SYSMAN IO REPLACE_WWID $2$MGA1
```
Configure Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.5 Fibre Channel Tape Support (Alpha)

Execute this command on each Alpha node in the cluster environment. You can accomplish this with the following commands:

```
$ MCR SYSMAN
SYSMAN> SET ENVIRONMENT/CLUSTERSYSMAN> IO REPLACE_WWID $2$MGA1
```

### 7.5.9 Determining the Physical Location of a Fibre Channel Tape Device

Given the name of a Fibre Channel tape device, it is helpful to know how to locate the Fibre Channel tape device. To do so, follow these steps:

1. From the system manager's account, run ANALYZE/SYSTEM.
2. At the SDA prompt, type CLUE SCSI/SUMMARY.
3. Search for the name of the device (for example, MGA3) in the column labeled DEVICE.
4. Note the corresponding value in the column labeled SCSI-LUN. This SCSI LUN value is the same value used by the MDR as the FC LUN. Also note the columns labeled Port and SCSI-ID for the device; all devices associated with that same port and SCSI-ID are attached to the same physical Fibre Channel port of the same MDR.
5. At the MDR console's AMC prompt, type `ShowFcScsiMap`. In the column labeled FC LUN, locate the value noted in step 4. Once you find the FC LUN value, note (on the same line) the corresponding values for SCSI Bus, SCSI Target ID, and SCSI LUN. This B:T:L information describes the physical location of the device within the MDR.

### 7.5.10 Accessing a Fibre Channel Tape Device in a Standalone Environment

Fibre Channel tape devices can be configured in the context of booting from the Version 7.3 CDROM distribution kit. The configuration steps are the same as the steps described in Section 7.5.4. Specifically, you must use the SYSMAN IO FIND_WWID and IO AUTOCONFIGURATION commands to configure the tape devices prior to use.

The file, SYS$DEVICES.DAT, is not created in this environment; therefore all pertinent naming information is stored in the memory data structures. Each time the CDROM is booted, you must repeat the IO FIND_WWID and IO AUTOCONFIGURE commands to name and configure the tape devices.

Note that the name of a Fibre Channel tape device in the CDROM boot environment does not persist through reboots, and may differ from the name that is assigned when booting from a read/write system disk.

### 7.5.11 Using an MDR with Dual Fibre Ports

Currently each Fibre Channel port on an MDR supports up to eight devices. A dual Fibre Channel port module allows support for 16 devices (two sets of eight devices each). To achieve proper load balancing between the two ports of a dual-port module, refer to the MDR documentation for instructions on using Selective Storage Presentation (SSP) to assign a specific device to a specific MDR port.

**Note**

In OpenVMS Version 7.3, multiple paths to the same tape device are not supported.
Even if multiple paths exist (because of the presence of a dual Fibre port module, or even because of multiple KGPSA adapters in the host), only the first path detected during autoconfiguration is used. Therefore, it is important to issue the SSP load-balancing commands before issuing the SYMAN command IO AUTOCONFIGURE. Also note that, when multiple paths exist to a Fibre Channel tape device, the SYMAN command IO FIND_WWID will continue to detect and report the presence of the device on such extraneous paths, even though IO AUTOCONFIGURE will not subsequently configure or otherwise allow access to the device on those paths.

7.6 Using the AlphaServer Console for Configuring FC

The AlphaServer console can be used to view the status of an FC interconnect. This allows you to confirm that the interconnect is set up properly before booting. If you plan to use an FC disk device for booting or dumping, you must perform some additional steps to set up those FC disk devices at the console. These topics are discussed in the next sections.

7.6.1 Viewing the FC Configuration from the Console

Console SHOW commands can be used to display information about the devices that the console detected when it last probed the system's I/O adapters. Unlike other interconnects, however, FC disk devices are not automatically included in the SHOW DEVICE output. This is because FC devices are identified by their WWIDs, and WWIDs are too large to be included in the SHOW DEVICE output. Instead, the console provides a command for managing WWIDs, named the wwidmgr command. This command enables you to display information about FC devices and to define appropriate device names for the FC devices that will be used for booting and dumping.

Note the following points about using the wwidmgr command:

- To use the wwidmgr command, if your system is an AlphaServer model 8x00, 4x00, or 1200, you must first enter diagnostic mode. On all other platforms, the wwidmgr command can be issued at any time.

- The changes made by the wwidmgr command do not take effect until after the next system initialization. After using the wwidmgr command, you must issue the initialize command.

Refer to the Wwidmgr User's Manual for a complete description of the wwidmgr command.

The following examples, produced on an AlphaServer 4100 system, show some typical uses of the wwidmgr command. Other environments may require additional steps to be taken, and the output on other systems may vary slightly.

Note the following about Example 7–1:

- The wwidmgr -show wwid command displays a summary of the FC devices on the system. This command does not display information about device connectivity.

- There are two FC adapters and five disks. (All the disks are listed at the end, independent of the adapters to which they are connected.) In this example, each of the disks was assigned a device identifier at the HSG80 console. The console refers to this identifier as a user-assigned device identifier (UDID).
Example 7–1 Using `wwidmgr -show wwid`

P00>>>set mode diag
Console is in diagnostic mode
P00>>>wwidmgr -show wwid
polling kgpsa0 (KGPSA-B) slot 2, bus 0 PCI, hose 1
kgpsa0.0.0.2.1  PGA0  WWN 1000-0000-c920-a7db
polling kgpsa1 (KGPSA-B) slot 3, bus 0 PCI, hose 1
kgpsa0.0.0.3.1  PGBO  WWN 1000-0000-c920-a694

Example 7–2 shows how the `wwidmgr show wwid -full` command displays information about FC devices and how they are connected. The display has two parts:

- The first part lists each path from an adapter to an FC port. Adapters are identified by console device names, such as KGPSAA. FC ports are identified by their WWID, such as 5000-1FE1-0000-0D14. If any FC disks are found on a path, they are listed after that path. FC disks are identified by their current console device name, followed by their WWID.

- The second part of the display lists all the FC disks and the paths through which they are reachable. In this part, which begins with `[0] UDID:10...`, you will see there are four paths to each disk with two paths through each adapter, KGPSAA and KGPSAB. Each path through an adapter goes to a different port on the HSG80. The column titled `Con` indicates whether the FC disk unit is currently online to the HSG80 controller that this path uses.

Example 7–2 Using `wwidmgr -show wwid -full`

P00>>>wwidmgr -show wwid -full

7.6.2 Setting Up FC Disks for Booting and Dumping

You must use the wwidmgr command to set up each device that you will use for booting or dumping. Once a device is set up, the console retains the information it requires to access the device in nonvolatile memory. You only have to rerun the wwidmgr command if the system configuration changes and the nonvolatile information is no longer valid.

The console provides a simplified setup command, called wwidmgr -quickset. This command can be used in either of the following cases:

- You are setting up just one device.
- All the devices you are setting up are accessed through the same ports on the HSG.

If neither description applies to your configuration, refer to the Wwidmgr User's Manual for additional instructions.

Example 7–3 illustrates the wwidmgr -quickset command. Note the following:

- The command wwidmgr -quickset -udid 10 sets up the FC disk whose HSG80 device identifier is equal to 10.
- The console device names are path dependent. Each path used to access an FC disk has a different name. In this example, the wwidmgr -quickset command establishes four console device names corresponding to the four paths from the host to the FC disk:
  - dga10.1001.0.2.1
  - dga10.1002.0.2.1
  - dgb10.1003.0.3.1
  - dgb10.1004.0.3.1
- The second command, wwidmgr -quickset -udid 50, sets up the FC disk whose HSG80 identifier is equal to 50.
- The changes made by the wwidmgr command do not take effect until after the next system initialization, so the next step is to issue an initialize command.
- After the initialization, the console show device command displays each FC adapter, followed by the paths through that adapter to each of the defined FC disks. The path-independent OpenVMS device name for each FC disk is displayed in the second column.
Example 7–3 Using `widmgr -quickset`

```
P00>>>wwidmgr -quickset -udid 10
```

Disk assignment and reachability after next initialization:

```
6000-1fe1-0000-0d10-0009-8090-0677-0016
via adapter: via fc nport: connected:
dga10.1001.0.2.1 kgsa0.0.0.2.1 5000-1fe1-0000-0d14 Yes
dga10.1002.0.2.1 kgsa0.0.0.2.1 5000-1fe1-0000-0d11 No
dgb10.1003.0.3.1 kgsab0.0.0.3.1 5000-1fe1-0000-0d13 Yes
dgb10.1004.0.3.1 kgsab0.0.0.3.1 5000-1fe1-0000-0d12 No
```

```
P00>>>wwidmgr -quickset -udid 50
```

Disk assignment and reachability after next initialization:

```
6000-1fe1-0000-0d10-0009-8090-0677-0026
via adapter: via fc nport: connected:
dga50.1001.0.2.1 kgsa0.0.0.2.1 5000-1fe1-0000-0d14 Yes
dga50.1002.0.2.1 kgsa0.0.0.2.1 5000-1fe1-0000-0d11 No
dgb50.1003.0.3.1 kgsab0.0.0.3.1 5000-1fe1-0000-0d13 Yes
dgb50.1004.0.3.1 kgsab0.0.0.3.1 5000-1fe1-0000-0d12 No
```

Example 7–4 shows a boot sequence from an FC system disk. Note the following:

- The boot device is `$1$DGA50`. The user has elected to enter all four paths to the device in the `bootdef_dev` string. This ensures that the system will be able to boot even if a path has failed.
The first path on the boot command string, dga50.1002.0.2.1, is not currently connected (that is, the disk is not on line to the HSG80 on that path). The console indicates this fact, retries a few times, then moves on to the next path in the bootdef_dev string. This path is currently connected, and the boot succeeds.

After booting, the OpenVMS SHOW DEVICE command confirms that OpenVMS has configured all five of the FC devices that were displayed by the wwidmgr -show wwid command, not only the two FC disks that were set up using the console wwidmgr -quickset command. The OpenVMS SHOW DEV/MULTIPATH command confirms that OpenVMS has configured all four paths to each disk.

Example 7-4 Boot Sequence from an FC System Disk

P00>>>set bootdef_dev dga50.1002.0.2.1,dga50.1001.0.2.1,dgb50.1003.0.3.1,

7.7 Setting Up an HSG for Use with OpenVMS

This section describes the basic requirements for setting up an HSG for use with OpenVMS. Note that the steps for setting up an HSG60 and an HSG80 are the same, although the examples show the output for an HSG80. Refer to the HSG80 Array Controller ACS Version 8.4 Configuration and CLI Reference Guide for more information.

These are the steps you must perform to configure an HSG for OpenVMS:

1. If the HSG has dual controllers, set them to multibus failover mode (Section 7.7.1).

2. Set the controller’s SCSI version to SCSI-3 (Section 7.7.2).

   Note: You do not need to set the controller’s allocation class value. This parameter is not used by OpenVMS with the HSG.

3. If you want to access the HSG Command Console LUN (CCL) from OpenVMS, assign it a device identifier (Section 7.7.3). This will cause OpenVMS to configure the CCL as a generic SCSI device.

   Note: In current versions of OpenVMS, you must assign a device identifier to the CCL. This requirement will be removed in a future update.

4. Set the parameters for the HSG FC ports (Section 7.7.4). Each port must have its FC profile set to PLDA and its topology set to FABRIC.

5. Initialize and add logical units to the HSG configuration (Section 7.7.5). In this step, you must assign a logical unit number and a device identifier to each logical unit.
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.7 Setting Up an HSG for Use with OpenVMS

Note
You do not need to set the logical unit’s preferred path parameter. OpenVMS does not use this value in its path selection.

6. Configure the HSG host connection table (Section 7.7.6).

7.7.1 Setting a Dual HSG to Multibus Failover Mode

To set a dual HSG to multibus failover mode, you can use the following commands at the HSG console:

- An initial SHOW command to show whether the dual controller is configured for failover.
- The SET command that puts the controllers into multibus mode. Notice that this causes the other controller to restart.
- A second SHOW command to show that the dual controller is configured for multibus failover.

The commands and output are shown in Example 7–5.

Example 7–5 Setting a Dual HSG to Multibus Failover Mode

HSG> SHOW THIS_CONTROLLER
Controller:
HSG80 ZG80900677 Software R024F-0, Hardware E01

  Expires: 27-APR-2000
  NOCACHE_UPS
Other controller restarted

7.7.2 Setting an HSG to SCSI-3 Mode

Example 7–6 shows how to set the HSG to SCSI-3 mode. Note that the other controller in a dual configuration is set automatically to the same mode. You must restart the controllers for this operation to take effect.

Example 7–6 Setting an HSG to SCSI-3 Mode

HSG> SET THIS_CONTROLLER SCSI_VERSION = SCSI-3
Warning 4030: Any units that would appear as unit 0 to a host will not be available when in SCSI-3 mode
Warning 4020: A restart of both this and the other controller is required before all the parameters modified will take effect
%CER--HSG> --13-JAN-1946 04:42:28 (time not set)-- Restart of this controller required
%CER--HSG> --13-JAN-1946 04:42:28 (time not set)-- Restart of the other controller required
Restart of this controller required
Restart of the other controller required
### 7.7.3 Setting the Device Identifier for the CCL

If you choose to have OpenVMS configure the CCL, then you must assign an identifier to the controller pair. This identifier must be unique for all HSG controller pairs in the cluster.

The following command sets the device identifier for the CCL of the controller pair to 42. This will cause OpenVMS to configure the CCL as a generic SCSI device. The device name will be $1$GGA42. Use the SHOW THIS_CONTROLLER command to verify the setting.

```
HSG> SET THIS_CONTROLLER IDENTIFIER = 42
```

---

**Note**

In current versions of OpenVMS, you must assign a device identifier to the CCL. This requirement will be removed in a future update.

---

### 7.7.4 Setting the HSG Port Parameters

To set each HSG port's profile to PLDA and its topology to FABRIC, use the commands shown in Example 7–7. You can verify the settings with the SHOW THIS and SHOW OTHER commands.

Note that each port has a unique 64-bit identifier in the form 5000-1FE1-0000-0D11. These identifiers are displayed in the SHOW THIS and SHOW OTHER displays, next to the label Reported PORT_ID. These identifiers are used by OpenVMS to denote the multiple paths that may exist between the host and the logical unit.

---

**Note**

The command `HSG> SET THIS_CONTROLLER PORT_1_PROFILE=PLDA`, shown in Example 7–7, is required for ACS 8.4. If you are using ACS 8.5 or above, omit this step.)
Example 7–7 Setting the HSG Port Parameters

HSG> SET THIS_CONTROLLER PORT_1_PROFILE = PLDA
Warning 4000: A restart of this controller is required before all the parameters modified will take effect

7.7.5 Setting Up Logical Units on the HSG

Setting up logical units on the HSG consists of the following steps, as shown in
Example 7–8:

1. Configure all the physical disk devices on the HSG with the CONFIG
command.
2. Configure each disk device as a logical unit as follows:
   a. Use the INITIALIZE command to initialize the disk.
   b. Use the ADD command to add the initialized disk as a host-visible logical unit.
      
      Choose a logical unit number that is unique for the HSG storage subsystem. The value chosen in Example 7–8 is 20, which results in a logical unit name of D20.
   c. Use the SET command to set a device identifier that will serve as the basis for the OpenVMS device name.
      
      This device identifier must be unique for all FC disks in the OpenVMS Cluster. The value chosen in Example 7–8 is 32020, which results in an OpenVMS device name of $1$DGA32020 for the logical unit.
      
      Note: This device identifier is limited to 9999, if the FC device is MSCP served. This restriction will be removed in a future release.

Example 7–8 Setting Up Logical Units on the HSG

HSG> RUN CONFIG

Config Local Program Invoked

Config is building its tables and determining what devices exist on the subsystem. Please be patient.

add disk DISK10000 1 0 0
add disk DISK10100 1 1 0
add disk DISK10200 1 2 0
add disk DISK20000 2 0 0

7.7.6 Configuring the HSG Host Connections

You can allow the HSG to create default host-connection information automatically, or you can set host connection information manually, as described in the HSG80 Array Controller ACS Version 8.4 Configuration and CLI Reference Guide. If you use the automatic method, you will need to make some changes to the default settings.

Initially, the HSG has no host connections. Then, when hosts are connected to the FC interconnect and powered up, the HSG detects them and creates default connection information for them, as shown in Example 7–9. After this default information is created, you may want to rename the connections to values that have meaning in your environment, as shown in Example 7–9.

Then, you must:

• Set the operating system name to VMS for each connection, as shown in Example 7–9.

• Check that the unit offset value is set to zero (0) for each connection. If not, set to zero.

Example 7–9 Configuring the HSG Host Connections

7.8 Creating a Cluster with a Shared FC System Disk

To configure nodes in an OpenVMS Cluster system, you must execute the CLUSTER_CONFIG.COM (or CLUSTER_CONFIG_LAN.COM) command procedure. (You can run either the full version, which provides more information about most prompts, or the brief version.)

For the purposes of CLUSTER_CONFIG, a shared Fibre Channel (FC) bus is treated like a shared SCSI bus, except that the allocation class parameters do not apply to FC. The rules for setting node allocation class and port allocation class values remain in effect when parallel SCSI storage devices are present in a configuration that includes FC storage devices.

To configure a new OpenVMS Cluster system, you must first enable clustering on a single, or standalone, system. Then you can add additional nodes to the cluster.

Example 7–10 shows how to enable clustering using brief version of CLUSTER_CONFIG_LAN.COM on a standalone node called FCNOD1. At the end of the procedure, FCNOD1 reboots and forms a one-node cluster.
Example 7-11 shows how to run the brief version of CLUSTER_CONFIG_LAN.COM on FCNOD1 to add a second node, called FCNOD2, to form a two-node cluster. At the end of the procedure, the cluster is configured to allow FCNOD2 to boot off the same FC system disk as FCNOD1.

The following steps are common to both examples:

1. Select the default option [1] for ADD.
2. Answer Yes when CLUSTER_CONFIG_LAN.COM asks whether there will be a shared SCSI bus. SCSI in this context refers to FC as well as to parallel SCSI.
   
   The allocation class parameters are not affected by the presence of FC.
3. Answer No when the procedure asks whether the node will be a satellite.

Example 7–10  Enabling Clustering on a Standalone FC Node

$ @CLUSTER_CONFIG_LAN BRIEF

Cluster Configuration Procedure
Executing on an Alpha System

DECnet Phase IV is installed on this node.

The LAN, not DECnet, will be used for MOP downline loading.
This Alpha node is not currently a cluster member

MAIN MENU

1. ADD FCNOD1 to existing cluster, or form a new cluster.
2. MAKE a directory structure for a new root on a system disk.
3. DELETE a root from a system disk.
4. EXIT from this procedure.

Enter choice [1]: 1
Is the node to be a clustered node with a shared SCSI or Fibre Channel bus (Y/N)? Y

Note:
   Every cluster node must have a direct connection to every other node in the cluster. Since FCNOD1 will be a clustered node with a shared SCSI or FC bus, and Memory Channel, CI, and DSSI are not present, the LAN will be used for cluster communication.

Enter this cluster’s group number: 511
Enter this cluster’s password:
Re-enter this cluster’s password for verification:

Will FCNOD1 be a boot server [Y]? Y

Verifying LAN adapters in LANACP database...
Updating LANACP LAN server process volatile and permanent databases...

Note: The LANACP LAN server process will be used by FCNOD1 for boot serving satellites. The following LAN devices have been found:

Verifying LAN adapters in LANACP database...

<table>
<thead>
<tr>
<th>LAN TYPE</th>
<th>ADAPTER NAME</th>
<th>SERVICE STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet</td>
<td>EWA0</td>
<td>ENABLED</td>
</tr>
</tbody>
</table>

(continued on next page)
Example 7–10 (Cont.) Enabling Clustering on a Standalone FC Node

CAUTION: If you do not define port allocation classes later in this procedure for shared SCSI buses, all nodes sharing a SCSI bus must have the same non-zero ALLOCLASS value. If multiple nodes connect to a shared SCSI bus without the same allocation class for the bus, system booting will halt due to the error or IO AUTOCONFIGURE after boot will keep the bus offline.

Enter a value for FCNOD1’s ALLOCLASS parameter [0]: 5
Does this cluster contain a quorum disk [N]? N
Each shared SCSI bus must have a positive allocation class value. A shared bus uses a PK adapter. A private bus may use: PK, DR, DV.

When adding a node with SCSI-based cluster communications, the shared SCSI port allocation classes may be established in SYS$DEVICEDAT. Otherwise, the system’s disk allocation class will apply.

A private SCSI bus need not have an entry in SYS$DEVICEDAT. If it has an entry, its entry may assign any legitimate port allocation class value:

\n n where n = a positive integer, 1 to 32767 inclusive
0 no port allocation class and disk allocation class does not apply
-1 system’s disk allocation class applies (system parameter ALLOCLASS)

When modifying port allocation classes, SYS$DEVICEDAT must be updated for all affected nodes, and then all affected nodes must be rebooted. The following dialog will update SYS$DEVICEDAT on FCNOD1.

There are currently no entries in SYS$DEVICEDAT for FCNOD1.
After the next boot, any SCSI controller on FCNOD1 will use FCNOD1’s disk allocation class.

Assign port allocation class to which adapter [RETURN for none]: PKA
Port allocation class for PKA: 10

Assign port allocation class to which adapter [RETURN for none]: PKB
Port allocation class for PKB: 20

WARNING: FCNOD1 will be a voting cluster member. EXPECTED_VOTES for this and every other cluster member should be adjusted at a convenient time before a reboot. For complete instructions, check the section on configuring a cluster in the "OpenVMS Cluster Systems" manual.

Execute AUTOGEN to compute the SYSGEN parameters for your configuration and reboot FCNOD1 with the new parameters. This is necessary before FCNOD1 can become a cluster member.

Do you want to run AUTOGEN now [Y]? Y
Running AUTOGEN -- Please wait.

The system is shutting down to allow the system to boot with the generated site-specific parameters and installed images.

The system will automatically reboot after the shutdown and the upgrade will be complete.
Example 7–11  Adding a Node to a Cluster with a Shared FC System Disk

$ @CLUSTER_CONFIG_LAN BRIEF
Cluster Configuration Procedure
Executing on an Alpha System

DEcnet Phase IV is installed on this node.
The LAN, not DEcnet, will be used for MOP downline loading.
FCNOD1 is an Alpha system and currently a member of a cluster
so the following functions can be performed:

MAIN MENU
1. ADD an Alpha node to the cluster.
2. REMOVE a node from the cluster.
3. CHANGE a cluster member’s characteristics.
4. CREATE a duplicate system disk for FCNOD1.
5. MAKE a directory structure for a new root on a system disk.
6. DELETE a root from a system disk.
7. EXIT from this procedure.

Enter choice [1]: 1

This ADD function will add a new Alpha node to the cluster.

WARNING: If the node being added is a voting member, EXPECTED_VOTES for
every cluster member must be adjusted. For complete instructions
check the section on configuring a cluster in the "OpenVMS Cluster Systems" manual.

CAUTION: If this cluster is running with multiple system disks and
common system files will be used, please, do not proceed
unless appropriate logical names are defined for cluster
common files in SYLOGICALS.COM. For instructions, refer to
the "OpenVMS Cluster Systems" manual.

Is the node to be a clustered node with a shared SCSI or Fibre Channel bus (Y/N)? Y
Will the node be a satellite [Y]? N
What is the node’s SCS node name? FCNOD2
What is the node’s SCSSYSTEMID number? 19.111
  NOTE: 19.111 equates to an SCSSYSTEMID of 19567
Will FCNOD2 be a boot server [Y]? Y
What is the device name for FCNOD2’s system root
[default DISK$V72_SSB:]? Y
What is the name of FCNOD2’s system root [SYS10]?
  Creating directory tree SYS10 ...
  System root SYS10 created

CAUTION: If you do not define port allocation classes later in this
procedure for shared SCSI buses, all nodes sharing a SCSI bus
must have the same non-zero ALLOCLASS value. If multiple
nodes connect to a shared SCSI bus without the same allocation
class for the bus, system booting will halt due to the error or
IO AUTOCONFIGURE after boot will keep the bus offline.

Enter a value for FCNOD2’s ALLOCLASS parameter [5]:
Does this cluster contain a quorum disk [N]? N
Size of pagefile for FCNOD2 [RETURN for AUTOGEN sizing]?
  A temporary pagefile will be created until resizing by AUTOGEN. The
default size below is arbitrary and may or may not be appropriate.

Size of temporary pagefile [10000]?
Size of swap file for FCNOD2 [RETURN for AUTOGEN sizing]?
  A temporary swap file will be created until resizing by AUTOGEN. The
default size below is arbitrary and may or may not be appropriate.

(continued on next page)
Configuring Fibre Channel as an OpenVMS Cluster Storage Interconnect
7.8 Creating a Cluster with a Shared FC System Disk

Example 7–11 (Cont.) Adding a Node to a Cluster with a Shared FC System Disk

Size of temporary swap file [8000]?
Each shared SCSI bus must have a positive allocation class value. A shared bus uses a PK adapter. A private bus may use: PK, DR, DV.

When adding a node with SCSI-based cluster communications, the shared SCSI port allocation classes may be established in SYS$DEVICES.DAT. Otherwise, the system’s disk allocation class will apply.

A private SCSI bus need not have an entry in SYS$DEVICES.DAT. If it has an entry, its entry may assign any legitimate port allocation class value:

- \( n \) where \( n \) = a positive integer, 1 to 32767 inclusive
- 0 no port allocation class and disk allocation class does not apply
- -1 system’s disk allocation class applies (system parameter ALLOCLASS)

When modifying port allocation classes, SYS$DEVICES.DAT must be updated for all affected nodes, and then all affected nodes must be rebooted. The following dialog will update SYS$DEVICES.DAT on FCNOD2.

Enter [RETURN] to continue:

$20$DKA400:<VMS$COMMON.SYSEXE>SYS$DEVICES.DAT;1 contains port allocation classes for FCNOD2. After the next boot, any SCSI controller not assigned in SYS$DEVICES.DAT will use FCNOD2’s disk allocation class.

Assign port allocation class to which adapter [RETURN for none]: PKA
Port allocation class for PKA: 11

Assign port allocation class to which adapter [RETURN for none]: PKB
Port allocation class for PKB: 20

Assign port allocation class to which adapter [RETURN for none]:

WARNING: FCNOD2 must be rebooted to make port allocation class specifications in SYS$DEVICES.DAT take effect.

Will a disk local only to FCNOD2 (and not accessible at this time to FCNOD1) be used for paging and swapping (Y/N)? N

If you specify a device other than DISK$V72_SSB: for FCNOD2’s page and swap files, this procedure will create PAGEFILE_FCNOD2.SYS and SWAPFILE_FCNOD2.SYS in the [SYSEXE] directory on the device you specify.

What is the device name for the page and swap files [DISK$V72_SSB:]?

%SYSGEN-I-CREATED, $20$DKA400:[SYS10.SYSEXE]PAGEFILE.SYS;1 created
%SYSGEN-I-CREATED, $20$DKA400:[SYS10.SYSEXE]SWAPFILE.SYS;1 created

The configuration procedure has completed successfully.

FCNOD2 has been configured to join the cluster.

The first time FCNOD2 boots, NETCONFIG.COM and AUTOGEN.COM will run automatically.
7.9 Online Reconfiguration

The FC interconnect can be reconfigured while the hosts are running OpenVMS. This includes the ability to:

- Add, move, or remove FC switches and HSGs.
- Add, move, or remove HSG virtual disk units.
- Change the device identifier or LUN value of the HSG virtual disk units.
- Disconnect and reconnect FC cables. Reconnection can be to the same or different adapters, switch ports, or HSG ports.

OpenVMS does not automatically detect most FC reconfigurations. You must use the following procedure to safely perform an FC reconfiguration, and to ensure that OpenVMS has adjusted its internal data structures to match the new state:

1. Dismount all disks that are involved in the reconfiguration.
2. Perform the reconfiguration.
3. Enter the following commands on each host that is connected to the Fibre Channel:
   
   SYSMAN> IO SCSI_PATH_VERIFY
   SYSMAN> IO AUTOCONFIGURE

   The purpose of the SCSI_PATH_VERIFY command is to check each FC path in the system's IO database to determine whether the attached device has been changed. If a device change is detected, then the FC path is disconnected in the IO database. This allows the path to be reconfigured for a new device by using the IO AUTOCONFIGURE command.

   ________________ Note ________________

   In the current release, the SCSI_PATH_VERIFY command only operates on FC disk devices. It does not operate on generic FC devices, such as the HSG command console LUN (CCL). (Generic FC devices have names such as $1$GGAnnnnn. This means that once the CCL of an HSG has been configured by OpenVMS with a particular device identifier, its device identifier should not be changed.

   ________________
Availability is the percentage of time that a computing system provides application service. By taking advantage of OpenVMS Cluster features, you can configure your OpenVMS Cluster system for various levels of availability, including disaster tolerance.

This chapter provides strategies and sample optimal configurations for building a highly available OpenVMS Cluster system. You can use these strategies and examples to help you make choices and tradeoffs that enable you to meet your availability requirements.

8.1 Availability Requirements

You can configure OpenVMS Cluster systems for different levels of availability, depending on your requirements. Most organizations fall into one of the broad (and sometimes overlapping) categories shown in Table 8–1.

<table>
<thead>
<tr>
<th>Availability Requirements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conventional</td>
<td>For business functions that can wait with little or no effect while a system or application is unavailable.</td>
</tr>
<tr>
<td>24 x 365</td>
<td>For business functions that require uninterrupted computing services, either during essential time periods or during most hours of the day throughout the year. Minimal down time is acceptable.</td>
</tr>
<tr>
<td>Disaster tolerant</td>
<td>For business functions with stringent availability requirements. These businesses need to be immune to disasters like earthquakes, floods, and power failures.</td>
</tr>
</tbody>
</table>

8.2 How OpenVMS Clusters Provide Availability

OpenVMS Cluster systems offer the following features that provide increased availability:

- A highly integrated environment that allows multiple systems to share access to resources
- Redundancy of major hardware components
- Software support for failover between hardware components
- Software products to support high availability
8.2.1 Shared Access to Storage

In an OpenVMS Cluster environment, users and applications on multiple systems can transparently share storage devices and files. When you shut down one system, users can continue to access shared files and devices. You can share storage devices in two ways:

- **Direct access**
  Connect disk and tape storage subsystems to CI and DSSI interconnects rather than to a node. This gives all nodes attached to the interconnect shared access to the storage system. The shutdown or failure of a system has no effect on the ability of other systems to access storage.

- **Served access**
  Storage devices attached to a node can be served to other nodes in the OpenVMS Cluster. MSCP and TMSCP server software enable you to make local devices available to all OpenVMS Cluster members. However, the shutdown or failure of the serving node affects the ability of other nodes to access storage.

8.2.2 Component Redundancy

OpenVMS Cluster systems allow for redundancy of many components, including:

- **Systems**
- **Interconnects**
- **Adapters**
- **Storage devices and data**

With redundant components, if one component fails, another is available to users and applications.

8.2.3 Failover Mechanisms

OpenVMS Cluster systems provide failover mechanisms that enable recovery from a failure in part of the OpenVMS Cluster. Table 8–2 lists these mechanisms and the levels of recovery that they provide.

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>What Happens if a Failure Occurs</th>
<th>Type of Recovery</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECnet-Plus cluster alias</td>
<td>If a node fails, OpenVMS Cluster software automatically distributes new incoming connections among other participating nodes.</td>
<td>Manual. Users who were logged in to the failed node can reconnect to a remaining node. Automatic for appropriately coded applications. Such applications can reinstate a connection to the cluster alias node name, and the connection is directed to one of the remaining nodes.</td>
</tr>
<tr>
<td>I/O paths</td>
<td>With redundant paths to storage devices, if one path fails, OpenVMS Cluster software fails over to a working path, if one exists.</td>
<td>Transparent, provided another working path is available.</td>
</tr>
</tbody>
</table>
## 8.2 How OpenVMS Clusters Provide Availability

### Table 8-2 (Cont.) Failover Mechanisms

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>What Happens if a Failure Occurs</th>
<th>Type of Recovery</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interconnect</td>
<td>With redundant or mixed interconnects, OpenVMS Cluster software uses the fastest working path to connect to other OpenVMS Cluster members. If an interconnect path fails, OpenVMS Cluster software fails over to a working path, if one exists.</td>
<td>Transparent.</td>
</tr>
<tr>
<td>Boot and disk servers</td>
<td>If you configure at least two nodes as boot and disk servers, satellites can continue to boot and use disks if one of the servers shuts down or fails. Failure of a boot server does not affect nodes that have already booted, providing they have an alternate path to access MSCP served disks.</td>
<td>Automatic.</td>
</tr>
<tr>
<td>Terminal servers and LAT software</td>
<td>Attach terminals and printers to terminal servers. If a node fails, the LAT software automatically connects to one of the remaining nodes. In addition, if a user process is disconnected from a LAT terminal session, when the user attempts to reconnect to a LAT session, LAT software can automatically reconnect the user to the disconnected session.</td>
<td>Manual.</td>
</tr>
<tr>
<td>Generic batch and print queues</td>
<td>You can set up generic queues to feed jobs to execution queues (where processing occurs) on more than one node. If one node fails, the generic queue can continue to submit jobs to execution queues on remaining nodes. In addition, batch jobs submitted using the /RESTART qualifier are automatically restarted on one of the remaining nodes.</td>
<td>Transparent for jobs waiting to be dispatched. Automatic or manual for jobs executing on the failed node.</td>
</tr>
<tr>
<td>Autostart batch and print queues</td>
<td>For maximum availability, you can set up execution queues as autostart queues with a failover list. When a node fails, an autostart execution queue and its jobs automatically fail over to the next logical node in the failover list and continue processing on another node. Autostart queues are especially useful for print queues directed to printers that are attached to terminal servers.</td>
<td>Transparent.</td>
</tr>
</tbody>
</table>

**Reference:** For more information about cluster alias, generic queues, and autostart queues, see OpenVMS Cluster Systems.

### 8.2.4 Related Software Products

Table 8-3 shows a variety of related OpenVMS Cluster software products that Compaq offers to increase availability.

### Table 8-3 Products That Increase Availability

<table>
<thead>
<tr>
<th>Product</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECamds</td>
<td>Collects and analyzes data from multiple nodes simultaneously and directs all output to a centralized DECwindows display. The analysis detects availability problems and suggests corrective actions.</td>
</tr>
<tr>
<td>Volume Shadowing for OpenVMS</td>
<td>Makes any disk in an OpenVMS Cluster system a redundant twin of any other same-size disk (same number of physical blocks) in the OpenVMS Cluster.</td>
</tr>
<tr>
<td>DEEvent</td>
<td>Simplifies disk monitoring. DEEvent notifies you when it detects that a disk may fail.</td>
</tr>
</tbody>
</table>
8.3 Strategies for Configuring Highly Available OpenVMS Clusters

The hardware you choose and the way you configure it has a significant impact on the availability of your OpenVMS Cluster system. This section presents strategies for designing an OpenVMS Cluster configuration that promotes availability.

8.3.1 Availability Strategies

Table 8–4 lists strategies for configuring a highly available OpenVMS Cluster. These strategies are listed in order of importance, and many of them are illustrated in the sample optimal configurations shown in this chapter.

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eliminate single points of failure</td>
<td>Make components redundant so that if one component fails, the other is available to take over.</td>
</tr>
<tr>
<td>Shadow system disks</td>
<td>The system disk is vital for node operation. Use Volume Shadowing for OpenVMS to make system disks redundant.</td>
</tr>
<tr>
<td>Shadow essential data disks</td>
<td>Use Volume Shadowing for OpenVMS to improve data availability by making data disks redundant.</td>
</tr>
<tr>
<td>Provide shared, direct access to storage</td>
<td>Where possible, give all nodes shared direct access to storage. This reduces dependency on MSCP server nodes for access to storage.</td>
</tr>
<tr>
<td>Minimize environmental risks</td>
<td>Take the following steps to minimize the risk of environmental problems:</td>
</tr>
<tr>
<td></td>
<td>• Provide a generator or uninterruptible power system (UPS) to replace utility power for use during temporary outages.</td>
</tr>
<tr>
<td></td>
<td>• Configure extra air-conditioning equipment so that failure of a single unit does not prevent use of the system equipment.</td>
</tr>
<tr>
<td>Configure at least three nodes</td>
<td>OpenVMS Cluster nodes require a quorum to continue operating. An optimal configuration uses a minimum of three nodes so that if one node becomes unavailable, the two remaining nodes maintain quorum and continue processing.</td>
</tr>
<tr>
<td>Reference:</td>
<td>For detailed information on quorum strategies, see Section 11.5 and OpenVMS Cluster Systems.</td>
</tr>
<tr>
<td>Configure extra capacity</td>
<td>For each component, configure at least one unit more than is necessary to handle capacity. Try to keep component use at 80% of capacity or less. For crucial components, keep resource use sufficiently less than 80% capacity so that if one component fails, the work load can be spread across remaining components without overloading them.</td>
</tr>
<tr>
<td>Keep a spare component on standby</td>
<td>For each component, keep one or two spares available and ready to use if a component fails. Be sure to test spare components regularly to make sure they work. More than one or two spare components increases complexity as well as the chance that the spare will not operate correctly when needed.</td>
</tr>
<tr>
<td>Use homogeneous nodes</td>
<td>Configure nodes of similar size and performance to avoid capacity overloads in case of failover. If a large node fails, a smaller node may not be able to handle the transferred work load. The resulting bottleneck may decrease OpenVMS Cluster performance.</td>
</tr>
<tr>
<td>Use reliable hardware</td>
<td>Consider the probability of a hardware device failing. Check product descriptions for MTBF (mean time between failures). In general, newer technologies are more reliable.</td>
</tr>
</tbody>
</table>
8.4 Strategies for Maintaining Highly Available OpenVMS Clusters

Achieving high availability is an ongoing process. How you manage your OpenVMS Cluster system is just as important as how you configure it. This section presents strategies for maintaining availability in your OpenVMS Cluster configuration.

8.4.1 Strategies for Maintaining Availability

After you have set up your initial configuration, follow the strategies listed in Table 8–5 to maintain availability in OpenVMS Cluster system.

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plan a failover strategy</td>
<td>OpenVMS Cluster systems provide software support for failover between hardware components. Be aware of what failover capabilities are available and which can be customized for your needs. Determine which components must recover from failure, and make sure that components are able to handle the additional work load that may result from a failover. Reference: Table 8–2 lists OpenVMS Cluster failover mechanisms and the levels of recovery that they provide.</td>
</tr>
<tr>
<td>Code distributed applications</td>
<td>Code applications to run simultaneously on multiple nodes in an OpenVMS Cluster system. If a node fails, the remaining members of the OpenVMS Cluster system are still available and continue to access the disks, tapes, printers, and other peripheral devices that they need.</td>
</tr>
<tr>
<td>Minimize change</td>
<td>Assess carefully the need for any hardware or software change before implementing it on a running node. If you must make a change, test it in a noncritical environment before applying it to your production environment.</td>
</tr>
<tr>
<td>Reduce size and complexity</td>
<td>After you have achieved redundancy, reduce the number of components and the complexity of the configuration. A simple configuration minimizes the potential for user and operator errors as well as hardware and software errors.</td>
</tr>
<tr>
<td>Set polling timers identically on all nodes</td>
<td>Certain system parameters control the polling timers used to maintain an OpenVMS Cluster system. Make sure these system parameter values are set identically on all OpenVMS Cluster member nodes. Reference: For information about these system parameters, see OpenVMS Cluster Systems.</td>
</tr>
<tr>
<td>Manage proactively</td>
<td>The more experience your system managers have, the better. Allow privileges for only those users or operators who need them. Design strict policies for managing and securing the OpenVMS Cluster system.</td>
</tr>
<tr>
<td>Use AUTOGEN proactively</td>
<td>With regular AUTOGEN feedback, you can analyze resource usage that may affect system parameter settings.</td>
</tr>
<tr>
<td>Reduce dependencies on a single server or disk</td>
<td>Distributing data across several systems and disks prevents one system or disk from being a single point of failure.</td>
</tr>
<tr>
<td>Implement a backup strategy</td>
<td>Performing frequent backup procedures on a regular basis guarantees the ability to recover data after failures. None of the strategies listed in this table can take the place of a solid backup strategy.</td>
</tr>
</tbody>
</table>

8.5 Availability in a LAN OpenVMS Cluster

Figure 8–1 shows an optimal configuration for a small-capacity, highly available LAN OpenVMS Cluster system. Figure 8–1 is followed by an analysis of the configuration that includes:

• Analysis of its components
Configuring OpenVMS Clusters for Availability
8.5 Availability in a LAN OpenVMS Cluster

- Advantages and disadvantages
- Key availability strategies implemented

Figure 8–1  LAN OpenVMS Cluster System
8.5.1 Components

The LAN OpenVMS Cluster configuration in Figure 8–1 has the following components:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1         | Two Ethernet interconnects. For higher network capacity, use FDDI interconnects instead of Ethernet.  
**Rationale:** For redundancy, use at least two LAN interconnects and attach all nodes to all LAN interconnects.  
A single interconnect would introduce a single point of failure. |
| 2         | Three to eight Ethernet-capable OpenVMS nodes.  
**Rationale:** Use at least three nodes to maintain quorum. Use fewer than eight nodes to avoid the complexity of managing eight system disks.  
**Alternative 1:** If you require satellite nodes, configure one or two nodes as boot servers. Note, however, that the availability of the satellite nodes is dependent on the availability of the server nodes.  
**Alternative 2:** For more than eight nodes, use a LAN OpenVMS Cluster configuration as described in Section 8.10. |
| 3         | System disks.  
System disks generally are not shadowed in LAN OpenVMS Clusters because of boot-order dependencies.  
**Alternative 1:** Shadow the system disk across two local controllers.  
**Alternative 2:** Shadow the system disk across two nodes. The second node mounts the disk as a nonsystem disk.  
**Reference:** See Section 11.2.4 for an explanation of boot-order and satellite dependencies. |
| 4         | Essential data disks.  
Use volume shadowing to create multiple copies of all essential data disks. Place shadow set members on at least two nodes to eliminate a single point of failure. |

8.5.2 Advantages

This configuration offers the following advantages:

- Lowest cost of all the sample configurations shown in this chapter.
- Some potential for growth in size and performance.
- The LAN interconnect supports the widest choice of nodes.

8.5.3 Disadvantages

This configuration has the following disadvantages:

- No shared direct access to storage. The nodes are dependent on an MSCP server for access to shared storage.
- Shadowing disks across the LAN nodes causes shadow copies when the nodes boot.
- Shadowing the system disks is not practical because of boot-order dependencies.
8.5.4 Key Availability Strategies
The configuration in Figure 8–1 incorporates the following strategies, which are critical to its success:

- This configuration has no single point of failure.
- Volume shadowing provides multiple copies of essential data disks across separate nodes.
- At least three nodes are used for quorum, so the OpenVMS Cluster continues if any one node fails.
- Each node has its own system disk; there are no satellite dependencies.

8.6 Configuring Multiple LANs
Follow these guidelines to configure a highly available multiple LAN cluster:

- Bridge LAN segments together to form a single extended LAN.
- Provide redundant LAN segment bridges for failover support.
- Configure LAN bridges to pass the LAN and MOP multicast messages.

**Reference:** Refer to the documentation for your LAN bridge and to the documentation for RBMS, DECelms, or POLYCENTER Framework for more information about configuring LAN bridges to pass these multicast messages.

- Use the Local Area OpenVMS Cluster Network Failure Analysis Program to monitor and maintain network availability. (See OpenVMS Cluster Systems for more information.)
- Use the troubleshooting suggestions in OpenVMS Cluster Systems to diagnose performance problems with the SCS layer and the NISCA transport protocol.
- Keep LAN average utilization below 50%.

**Reference:** See Section 10.7.7 for information about extended LANs (ELANs).

8.6.1 Selecting MOP Servers
When using multiple LAN adapters with multiple LAN segments, distribute the connections to LAN segments that provide MOP service. The distribution allows MOP servers to downline load satellites even when network component failures occur.

It is important to ensure sufficient MOP servers for both VAX and Alpha nodes to provide downline load support for booting satellites. By careful selection of the LAN connection for each MOP server (Alpha or VAX, as appropriate) on the network, you can maintain MOP service in the face of network failures.
8.6.2 Configuring Two LAN Segments

Figure 8–2 shows a sample configuration for an OpenVMS Cluster system connected to two different LAN segments. The configuration includes Alpha and VAX nodes, satellites, and two bridges.

The figure illustrates the following points:

- Connecting critical nodes to multiple LAN segments provides increased availability in the event of segment or adapter failure. Disk and tape servers can use some of the network bandwidth provided by the additional network connection. Critical satellites can be booted using the other LAN adapter if one LAN adapter fails.

- Connecting noncritical satellites to only one LAN segment helps to balance the network load by distributing systems equally among the LAN segments. These systems communicate with satellites on the other LAN segment through one of the bridges.

- Only one LAN adapter per node can be used for DECnet and MOP service to prevent duplication of LAN addresses.

- LAN adapters providing MOP service (Alpha or VAX, as appropriate) should be distributed among the LAN segments to ensure that LAN failures do not prevent satellite booting.
8.6 Configuring Multiple LANs

- Using redundant LAN bridges prevents the bridge from being a single point of failure.

8.6.3 Configuring Three LAN Segments

Figure 8–3 shows a sample configuration for an OpenVMS Cluster system connected to three different LAN segments. The configuration also includes both Alpha and VAX nodes and satellites and multiple bridges.

Figure 8–3 Three-LAN Segment OpenVMS Cluster Configuration

The figure illustrates the following points:

- Connecting disk and tape servers to two or three LAN segments can help provide higher availability and better I/O throughput.

- Connecting critical satellites to two or more LAN segments can also increase availability. If any of the network components fails, these satellites can use the other LAN adapters to boot and still have access to the critical disk servers.

- Distributing noncritical satellites equally among the LAN segments can help balance the network load.
• A MOP server (Alpha or VAX, as appropriate) is provided for each LAN segment.

Reference: See Section 11.2.4 for more information about boot order and satellite dependencies in a LAN. See OpenVMS Cluster Systems for information about LAN bridge failover.

8.7 Availability in a DSSI OpenVMS Cluster

Figure 8–4 shows an optimal configuration for a medium-capacity, highly available DSSI OpenVMS Cluster system. Figure 8–4 is followed by an analysis of the configuration that includes:

• Analysis of its components
• Advantages and disadvantages
• Key availability strategies implemented
Figure 8–4  DSSI OpenVMS Cluster System

1. DSSI
2. CPU
3. Ethernet
4. System Disk
5. Data Disk

ZK-6639A-GE
8.7.1 Components

The DSSI OpenVMS Cluster configuration in Figure 8–4 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1    | Two DSSI interconnects with two DSSI adapters per node.  
**Rationale:** For redundancy, use at least two interconnects and attach all nodes to all DSSI interconnects. |
| 2    | Two to four DSSI-capable OpenVMS nodes.  
**Rationale:** Three nodes are recommended to maintain quorum. A DSSI interconnect can support a maximum of four OpenVMS nodes.  
**Alternative 1:** Two-node configurations require a quorum disk to maintain quorum if a node fails.  
**Alternative 2:** For more than four nodes, configure two DSSI sets of nodes connected by two LAN interconnects. |
| 3    | Two Ethernet interconnects.  
**Rationale:** The LAN interconnect is required for DECnet-Plus communication. Use two interconnects for redundancy. For higher network capacity, use FDDI instead of Ethernet. |
| 4    | System disk.  
Shadow the system disk across DSSI interconnects.  
**Rationale:** Shadow the system disk across interconnects so that the disk and the interconnect do not become single points of failure. |
| 5    | Data disks.  
Shadow essential data disks across DSSI interconnects.  
**Rationale:** Shadow the data disk across interconnects so that the disk and the interconnect do not become single points of failure. |

8.7.2 Advantages

The configuration in Figure 8–4 offers the following advantages:

- The DSSI interconnect gives all nodes shared, direct access to all storage.
- Moderate potential for growth in size and performance.
- There is only one system disk to manage.

8.7.3 Disadvantages

This configuration has the following disadvantages:

- Applications must be shut down in order to swap DSSI cables. This is referred to as “warm swap.” The DSSI cable is warm swappable for the adapter, the cable, and the node.
- A node’s location on the DSSI affects the recoverability of the node. If the adapter fails on a node located at the end of the DSSI interconnect, the OpenVMS Cluster may become unavailable.
8.7.4 Key Availability Strategies

The configuration in Figure 8–4 incorporates the following strategies, which are critical to its success:

- This configuration has no single point of failure.
- Volume shadowing provides multiple copies of system and essential data disks across separate DSSI interconnects.
- All nodes have shared, direct access to all storage.
- At least three nodes are used for quorum, so the OpenVMS Cluster continues if any one node fails.
- There are no satellite dependencies.

8.8 Availability in a CI OpenVMS Cluster

Figure 8–5 shows an optimal configuration for a large-capacity, highly available CI OpenVMS Cluster system. Figure 8–5 is followed by an analysis of the configuration that includes:

- Analysis of its components
- Advantages and disadvantages
- Key availability strategies implemented
8.8.1 Components

The CI OpenVMS Cluster configuration in Figure 8–5 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Two LAN interconnects.</td>
</tr>
</tbody>
</table>

**Rationale:** The additional use of LAN interconnects is required for DECnet-Plus communication. Having two LAN interconnects—Ethernet or FDDI—increases redundancy. For higher network capacity, use FDDI instead of Ethernet.
8.8 Availability in a CI OpenVMS Cluster

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2    | Two to 16 CI capable OpenVMS nodes.  
**Rationale:** Three nodes are recommended to maintain quorum. A CI interconnect can support a maximum of 16 OpenVMS nodes.  
**Reference:** For more extensive information about the CIPCA, see Appendix C.  
**Alternative:** Two-node configurations require a quorum disk to maintain quorum if a node fails. |
| 3    | Two CI interconnects with two star couplers.  
**Rationale:** Use two star couplers to allow for redundant connections to each node. |
| 4    | Critical disks are dual ported between CI storage controllers.  
**Rationale:** Connect each disk to two controllers for redundancy. Shadow and dual port system disks between CI storage controllers. Periodically alternate the primary path of dual-ported disks to test hardware. |
| 5    | Data disks.  
**Rationale:** Single port nonessential data disks, for which the redundancy provided by dual porting is unnecessary. |
| 6    | Essential data disks are shadowed across controllers.  
**Rationale:** Shadow essential disks and place shadow set members on different HSCs to eliminate a single point of failure. |

### 8.8.2 Advantages
This configuration offers the following advantages:

- All nodes have direct access to all storage.
- This configuration has a high growth capacity for processing and storage.
- The CI is inherently dual pathed, unlike other interconnects.

### 8.8.3 Disadvantages
This configuration has the following disadvantage:

- Higher cost than the other configurations.

### 8.8.4 Key Availability Strategies
The configuration in Figure 8–5 incorporates the following strategies, which are critical to its success:

- This configuration has no single point of failure.
- Dual porting and volume shadowing provides multiple copies of essential disks across separate HSC or HSJ controllers.
- All nodes have shared, direct access to all storage.
- At least three nodes are used for quorum, so the OpenVMS Cluster continues if any one node fails.
- There are no satellite dependencies.
- The uninterruptible power supply (UPS) ensures availability in case of a power failure.
8.9 Availability in a MEMORY CHANNEL OpenVMS Cluster

Figure 8–6 shows a highly available MEMORY CHANNEL (MC) cluster configuration. Figure 8–6 is followed by an analysis of the configuration that includes:

- Analysis of its components
- Advantages and disadvantages
- Key availability strategies implemented

8.9.1 Components

The MEMORY CHANNEL configuration shown in Figure 8–6 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Two MEMORY CHANNEL hubs.</td>
</tr>
</tbody>
</table>

*Rationale:* Having two hubs and multiple connections to the nodes prevents having a single point of failure.
### 8.9 Availability in a MEMORY CHANNEL OpenVMS Cluster

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2    | Three to eight MEMORY CHANNEL nodes.  
**Rationale:** Three nodes are recommended to maintain quorum. A MEMORY CHANNEL interconnect can support a maximum of eight OpenVMS Alpha nodes.  
**Alternative:** Two-node configurations require a quorum disk to maintain quorum if a node fails. |
| 3    | Fast-wide differential (FWD) SCSI bus.  
**Rationale:** Use a FWD SCSI bus to enhance data transfer rates (20 million transfers per second) and because it supports up to two HSZ controllers. |
| 4    | Two HSZ controllers.  
**Rationale:** Two HSZ controllers ensure redundancy in case one of the controllers fails. With two controllers, you can connect two single-ended SCSI buses and more storage. |
| 5    | Essential system disks and data disks.  
**Rationale:** Shadow essential disks and place shadow set members on different SCSI buses to eliminate a single point of failure. |

#### 8.9.2 Advantages

This configuration offers the following advantages:

- All nodes have direct access to all storage.
- SCSI storage provides low-cost, commodity hardware with good performance.
- The MEMORY CHANNEL interconnect provides high-performance, node-to-node communication at a low price. The SCSI interconnect complements MEMORY CHANNEL by providing low-cost, commodity storage communication.

#### 8.9.3 Disadvantages

This configuration has the following disadvantage:

- The fast-wide differential SCSI bus is a single point of failure. One solution is to add a second, fast-wide differential SCSI bus so that if one fails, the nodes can fail over to the other. To use this functionality, the systems must be running OpenVMS Version 7.2 or higher and have multipath support enabled.

#### 8.9.4 Key Availability Strategies

The configuration in Figure 8–6 incorporates the following strategies, which are critical to its success:

- Redundant MEMORY CHANNEL hubs and HSZ controllers prevent a single point of hub or controller failure.
- Volume shadowing provides multiple copies of essential disks across separate HSZ controllers.
- All nodes have shared, direct access to all storage.
- At least three nodes are used for quorum, so the OpenVMS Cluster continues if any one node fails.
8.10 Availability in an OpenVMS Cluster with Satellites

Satellites are systems that do not have direct access to a system disk and other OpenVMS Cluster storage. Satellites are usually workstations, but they can be any OpenVMS Cluster node that is served storage by other nodes in the cluster.

Because satellite nodes are highly dependent on server nodes for availability, the sample configurations presented earlier in this chapter do not include satellite nodes. However, because satellite/server configurations provide important advantages, you may decide to trade off some availability to include satellite nodes in your configuration.

Figure 8–7 shows an optimal configuration for a OpenVMS Cluster system with satellites. Figure 8–7 is followed by an analysis of the configuration that includes:

• Analysis of its components
• Advantages and disadvantages
• Key availability strategies implemented

The base configurations in Figure 8–4 and Figure 8–5 could replace the base configuration shown in Figure 8–7. In other words, the FDDI and satellite segments shown in Figure 8–7 could just as easily be attached to the configurations shown in Figure 8–4 and Figure 8–5.
8.10 Availability in an OpenVMS Cluster with Satellites

Figure 8–7 OpenVMS Cluster with Satellites
8.10 Availability in an OpenVMS Cluster with Satellites

8.10.1 Components

This satellite/server configuration in Figure 8–7 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1    | Base configuration.  
      The base configuration performs server functions for satellites. |
| 2    | Three to 16 OpenVMS server nodes.  
      **Rationale:** At least three nodes are recommended to maintain quorum. More than 16 nodes introduce excessive complexity. |
| 3    | FDDI ring between base server nodes and satellites.  
      **Rationale:** The FDDI ring has increased network capacity over Ethernet, which is slower.  
      **Alternative:** Use two Ethernet segments instead of the FDDI ring. |
| 4    | Two Ethernet segments from the FDDI ring to attach each critical satellite with two Ethernet adapters. Each of these critical satellites has its own system disk.  
      **Rationale:** Having their own boot disks increases the availability of the critical satellites. |
| 5    | For noncritical satellites, place a boot server on the Ethernet segment.  
      **Rationale:** Noncritical satellites do not need their own boot disks. |
| 6    | Limit the satellites to 15 per segment.  
      **Rationale:** More than 15 satellites on a segment may cause I/O congestion. |

8.10.2 Advantages

This configuration provides the following advantages:

- A large number of nodes can be served in one OpenVMS Cluster.
- You can spread a large number of nodes over a greater distance.

8.10.3 Disadvantages

This configuration has the following disadvantages:

- Satellites with single LAN adapters have a single point of failure that causes cluster transitions if the adapter fails.
- High cost of LAN connectivity for highly available satellites.

8.10.4 Key Availability Strategies

The configuration in Figure 8–7 incorporates the following strategies, which are critical to its success:

- This configuration has no single point of failure.
- The FDDI interconnect has sufficient bandwidth to serve satellite nodes from the base server configuration.
- All shared storage is MSCP served from the base configuration, which is appropriately configured to serve a large number of nodes.
8.11 Multiple-Site OpenVMS Cluster System

Multiple-site OpenVMS Cluster configurations contain nodes that are located at geographically separated sites. Depending on the technology used, the distances between sites can be as great as 150 miles. FDDI, asynchronous transfer mode (ATM), and DS3 are used to connect these separated sites to form one large cluster. Available from most common telephone service carriers, DS3 and ATM services provide long-distance, point-to-point communications for multiple-site clusters.

Figure 8–8 shows a typical configuration for a multiple-site OpenVMS Cluster system. Figure 8–8 is followed by an analysis of the configuration that includes:

- Analysis of components
- Advantages

8.11.1 Components

Although Figure 8–8 does not show all possible configuration combinations, a multiple-site OpenVMS Cluster can include:

- Two data centers with an intersite link (FDDI, ATM, or DS3) connected to a DEC concentrator or GIGAswitch crossbar switch.
- Intersite link performance that is compatible with the applications that are shared by the two sites.
Configuring OpenVMS Clusters for Availability
8.11 Multiple-Site OpenVMS Cluster System

• Up to 96 Alpha and VAX (combined total) nodes. In general, the rules that apply to OpenVMS LAN and extended LAN (ELAN) clusters also apply to multiple-site clusters.

Reference: For LAN configuration guidelines, see Section 4.12.6. For ELAN configuration guidelines, see Section 10.7.7.

8.11.2 Advantages

The benefits of a multiple-site OpenVMS Cluster system include the following:

• A few systems can be remotely located at a secondary site and can benefit from centralized system management and other resources at the primary site. For example, a main office data center could be linked to a warehouse or a small manufacturing site that could have a few local nodes with directly attached, site-specific devices. Alternatively, some engineering workstations could be installed in an office park across the city from the primary business site.

• Multiple sites can readily share devices such as high-capacity computers, tape libraries, disk archives, or phototypesetters.

• Backups can be made to archival media at any site in the cluster. A common example would be to use disk or tape at a single site to back up the data for all sites in the multiple-site OpenVMS Cluster. Backups of data from remote sites can be made transparently (that is, without any intervention required at the remote site).

• In general, a multiple-site OpenVMS Cluster provides all of the availability advantages of a LAN OpenVMS Cluster. Additionally, by connecting multiple, geographically separate sites, multiple-site OpenVMS Cluster configurations can increase the availability of a system or elements of a system in a variety of ways:
  – Logical volume/data availability—Volume shadowing or redundant arrays of independent disks (RAID) can be used to create logical volumes with members at both sites. If one of the sites becomes unavailable, data can remain available at the other site.
  – Site failover—By adjusting the VOTES system parameter, you can select a preferred site to continue automatically if the other site fails or if communications with the other site are lost.

Reference: For additional information about multiple-site clusters, see OpenVMS Cluster Systems.

8.12 Disaster-Tolerant OpenVMS Cluster Configurations

Disaster-tolerant OpenVMS Cluster configurations make use of Volume Shadowing for OpenVMS, high-speed networks, and specialized management software.

Disaster-tolerant OpenVMS Cluster configurations enable systems at two different geographic sites to be combined into a single, manageable OpenVMS Cluster system. Like the multiple-site cluster discussed in the previous section, these physically separate data centers are connected by FDDI or by a combination of FDDI and ATM, T3, or E3.
The OpenVMS disaster-tolerant product was formerly named the Business Recovery Server (BRS). BRS has been subsumed by a services offering named Disaster Tolerant Cluster Services, which is a system management and software service package. For more information about Disaster Tolerant Cluster Services, contact your Compaq Services representative.
There are many ways to configure a CI (cluster interconnect) OpenVMS Cluster system. This chapter describes how to configure CI OpenVMS Clusters to maximize both availability and performance. This is done by presenting a series of configuration examples of increasing complexity, followed by a comparative analysis of each example. These configurations illustrate basic techniques that can be scaled upward to meet the availability, I/O performance, and storage connectivity needs of very large clusters.

9.1 CI Components

The CI is a radial bus through which OpenVMS Cluster systems communicate with each other and with storage. The CI consists of the following components:

- CI host adapter
- HSJ or HSC storage controller
  An HSJ or HSC storage controller is optional but generally present.
- CI cables
  For each of the CI’s two independent paths (called path A and path B), there is a transmit and receive cable pair.
- Star coupler
  This is a passive device that serves as a common connection point for signals between OpenVMS nodes and HSC or HSJ controllers that are connected to the CI. A star coupler consists of two completely independent and electrically isolated “path hubs.” Each CI path hub is extremely reliable because it contains only transformers carrying low-power signals.

Availability and performance can both be increased by adding components. Components added for availability need to be configured so that a redundant component is available to assume the work being performed by a failed component. Components added for performance need to be configured so that the additional components can work in parallel with other components.

Frequently, you need to maximize both availability and performance. The techniques presented here are intended to help achieve these dual goals.
9.2 Configuration Assumptions

The configurations shown here are based on the following assumptions:

1. MSCP serving is enabled.
2. Volume Shadowing for OpenVMS is installed.
3. When performance is being discussed:
   a. CI host adapters are CIPCA or CIXCD.
      Older CI adapter models are significantly slower.
   b. CI storage controllers are HSJ 50s.
      Compared with HSJ 50s, HSJ 40s are somewhat slower, and HSC models are significantly slower.

9.3 Configuration 1

Configuration 1, shown in Figure 9–1, provides no single point of failure. Its I/O performance is limited by the bandwidth of the star coupler.

**Figure 9–1** Redundant HSJs and Host CI Adapters Connected to Same CI (Configuration 1)
9.3.1 Components

The CI configuration shown in Figure 9–1 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
</table>
| Host 1, Host 2 | Dual CI capable OpenVMS Alpha or VAX hosts.  
**Rationale:** Either host can fail and the system can continue. The full performance of both hosts is available for application use under normal conditions. |
| CI 1-1, CI 1-2, CI 2-1, CI 2-2 | Dual CI adapters on each host.  
**Rationale:** Either of a host’s CI adapters can fail and the host will retain CI connectivity to the other host and to the HSJ storage controllers. |
| Star Coupler | One star coupler cabinet containing two independent path hubs. The star coupler is redundantly connected to the CI host adapters and HSJ storage controllers by a transmit/receive cable pair per path.  
**Rationale:** Either of the path hubs or an attached cable could fail and the other CI path would continue to provide full CI connectivity. When both paths are available, their combined bandwidth is usable for host-to-host and host-to-storage controller data transfer. |
| HSJ 1, HSJ 2 | Dual HSJ storage controllers in a single StorageWorks cabinet.  
**Rationale:** Either storage controller can fail and the other controller can assume control of all disks by means of the SCSI buses shared between the two HSJ s. When both controllers are available, each can be assigned to serve a portion of the disks. Thus, both controllers can contribute their I/O-per-second and bandwidth capacity to the cluster. |
| SCSI 1, SCSI 2 | Shared SCSI buses between HSJ pairs.  
**Rationale:** Provide access to each disk on a shared SCSI from either HSJ storage controller. This effectively dual ports the disks on that bus. |
| Disk 1, Disk 2, . . . Disk n-1, Disk n | Critical disks are dual ported between HSJ pairs by shared SCSI buses.  
**Rationale:** Either HSJ can fail, and the other HSJ will assume control of the disks that the failed HSJ was controlling. |
| Shadow Set 1 through Shadow Set n | Essential disks are shadowed by another disk that is connected on a different shared SCSI.  
**Rationale:** A disk or the SCSI bus to which it is connected, or both, can fail, and the other shadow set member will still be available. When both disks are available, their combined READ I/O capacity and READ data bandwidth capacity are available to the cluster. |

9.3.2 Advantages

This configuration offers the following advantages:

- All nodes have direct access to storage.
- Highly expandable.
- CI is inherently dual pathed.
- No single component failure can disable the cluster.
- If a CI adapter fails, or both of its paths are disabled, OpenVMS will automatically fail over all I/O and cluster traffic to the other CI adapter.
- Disks are dual ported between HSJ controllers; automatic disk failover to the other controller if an HSJ fails or if an HSJ loses both paths to a star coupler.
9.3 Configuration 1

- Redundant storage controllers can be used to provide additional performance by dividing disks between the two storage controllers.

Disks can be assigned to HSJ storage controllers by the OpenVMS Prefer utility supplied in SYS$EXAMPLES, or by issuing a $QIO call with IO$_SETPRFPATH and IO$_M_FORCEPATH modifiers, or by using the HSJ SET_PREFERRED command (less desirable; use only for this configuration).

- Critical disks are shadowed with shadow set members on different SCSI buses.

- Read I/Os are automatically load balanced across shadow set members for performance.

- Lowest cost.

9.3.3 Disadvantages

This configuration has the following disadvantages:

- Second CI adapter in each host is unlikely to enhance performance.

- Both HSJ s have to share the bandwidth of a single CI.

- Failure of a CI path hub or path cable halves the bandwidth available to all CI components that use the failed component.

- Physical damage to a star coupler or associated cables is likely to disable the entire CI, rendering the cluster unusable.

- Physical damage to the StorageWorks cabinet could render the cluster unusable.

9.3.4 Key Availability and Performance Strategies

This configuration incorporates the following strategies:

- All components are duplicated.

- Redundant storage controllers are included.

- This configuration has no single point of failure.

- Dual porting and volume shadowing provide multiple copies of essential disks across separate HSJ controllers.

- All nodes have shared, direct access to all storage.

- A quorum disk allows other node to continue if one node fails. (Alternatively, at least three nodes could be used.)

9.4 Configuration 2

The configuration illustrated in Figure 9–2 with redundant HSJ s, host CI adapters, and CIs provides no electrical single point of failure. Its two star couplers provide increased I/O performance and availability over configuration 1.
Figure 9–2  Redundant HSJs and Host CI Adapters Connected to Redundant CIs (Configuration 2)

<tr>
<td><strong>Rationale:</strong></td>
<td>A disk or the SCSI bus to which it is connected, or both, can fail and the other shadow set member will still be available. When both disks are available, both can provide their READ I/O capacity and their READ data bandwidth capacity to the cluster.</td>
</tr>
</tbody>
</table>

### 9.4.2 Advantages

Configuration 2 offers all the advantages of Configuration 1 plus the following advantages:

- CI is likely to remain fully usable in the event of localized damage to a star coupler cabinet or to the cables connected to it.
- Failure of an HSJ, or an HSJ losing both paths to a star coupler host will result in the other HSJ assuming control of all dual-pathed disks.
- Host with connectivity will automatically MSCP serve unreachable disks to a host that has lost connectivity to an HSJ.
- Dual-pathed disks can be switched to an HSJ with full host connectivity if a host loses connectivity to an HSJ.

The disks on the HSJ that cannot be reached by a host can be reassigned to the HSJ with full connectivity by operator command, or by a DCL or other program that monitors for connectivity loss. You can assign disks to another storage controller with the Prefer utility supplied in SYS$EXAMPLES, or by issuing a $QIO call with IO$_SETPRFPATH and IO$_M_FORCEPATH modifiers, or by powering off the HSJ with reduced connectivity (less desirable).

The HSJ SET_PREFERRED command is **not** recommended in this configuration because this command can not be overridden by a host PREFER or IO$_SETPRFPATH modifier. A new SET_PREFERRED command assigning a device to another HSJ will not take effect until the HSJ, to which the device was assigned by a previous SET_PREFERRED command, is power cycled.)
9.4.3 Disadvantages

Configuration 2 has the following disadvantages:

- Host CI adapter failure will not cause disks to automatically fail over to an HSJ that still has full host connectivity.
  
  If a host CI adapter fails and if MSCP serving is enabled, then the other OpenVMS system will begin serving the unreachable HSJ’s disks to the host with the failed adapter.

- Physical damage to a star coupler or associated cables is likely to disable the entire CI, rendering the cluster unusable.

- Physical damage to the StorageWorks cabinet could render the cluster unusable.

- Higher cost than configuration 1.

9.4.4 Key Availability and Performance Strategies

Configuration 2 provides configuration 1 strategies, plus:

- Second CI provides additional redundancy.

- Second CI cables and star coupler are physically separate.

9.5 Configuration 3

The availability of a CI configuration can be further improved by physically separating the path A and path B CI cables and their associated path hubs. This significantly reduces the probability of a mechanical accident or other localized damage destroying both paths of a CI. This configuration is shown in Figure 9–3.
Configuration 3 is electrically identical to configuration 2. However, the path A and path B cables are physically separate for both CIs. The path A cables for both CI 1 and CI 2 are routed together to star coupler cabinet A, but are connected to different CI path hubs in that cabinet.

Similarly, the path B cables for both CIs go to different CI path hubs in star coupler cabinet B. The path-specific star coupler cabinets and associated path cables should be separated as much as possible. For example, the star coupler cabinets could be installed on opposite sides of a computer room, and the CI cables could be routed so that path A and path B cables follow different paths.

---

**Note**

The path separation technique illustrated for configuration 3 (Figure 9–3) can also be applied to configuration 1 (Figure 9–1). In this case, each star coupler cabinet would have only one path hub. The CI’s path A cables would go to the path hub in Star Coupler A. Similarly, the path B cables would go to Star Coupler B.
### 9.5.1 Components

The CI OpenVMS Cluster configuration shown in Figure 9–3 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host 1, Host 2</strong></td>
<td>Dual CI capable OpenVMS Alpha or VAX hosts. <strong>Rationale:</strong> Either host can fail and the system can continue. The full performance of both hosts is available for application use under normal conditions.</td>
</tr>
<tr>
<td><strong>CI 1-1, CI 1-2, CI 2-1, CI 2-2</strong></td>
<td>Dual CI adapters on each host. Adapter CI 1-n is Host 1’s CI adapter connected to CI n, and so on. <strong>Rationale:</strong> Either host’s CI adapters can fail and the host will retain CI connectivity to the other host and to the HSJ storage controllers. Each CI adapter on a host is connected to a different star coupler. In the absence of failures, the full data bandwidth and I/O-per-second capacity of both CI adapters is available to the host.</td>
</tr>
<tr>
<td><strong>Star Coupler A (Path A Hubs), Star Coupler B (Path B Hubs)</strong></td>
<td>Two CI star couplers, each comprising two independent path hubs. Star Coupler A’s path hubs are connected to path A cables for both CIs, and Star Coupler B’s path hubs are connected to path B cables for both CIs. <strong>Rationale:</strong> Mechanical or other localized damage to a star coupler or an attached cable would probably not affect the other CI paths. The other paths and star coupler would continue to provide full connectivity for both CIs. Loss of a path affects only the bandwidth available to the storage controllers and host adapters connected to the failed path. When all paths are available, the combined bandwidth of both CIs is usable.</td>
</tr>
<tr>
<td><strong>Path A CI Cables, Path B CI Cables</strong></td>
<td>Each path’s hub is connected to the CI host adapters and HSJ storage controllers by a transmit/receive cable pair per path. The path A cables of both CIs are routed together, but their routing differs from the routing of the path B cables.</td>
</tr>
<tr>
<td><strong>HSJ 1, HSJ 2</strong></td>
<td>Dual HSJ storage controllers in a single StorageWorks cabinet. <strong>Rationale:</strong> Either storage controller can fail and the other controller can control any disks the failed controller was handling by means of the SCSI buses shared between the two HSJs. When both controllers are available, each can be assigned to serve a subset of the disks. Thus, both controllers can contribute their I/O-per-second and bandwidth capacity to the cluster.</td>
</tr>
<tr>
<td><strong>SCSI 1, SCSI 2</strong></td>
<td>Shared SCSI buses connected between HSJ pairs. <strong>Rationale:</strong> Provide access to each disk on a shared SCSI bus from either HSJ storage controller. This effectively dual ports the disks on that bus.</td>
</tr>
<tr>
<td><strong>Disk 1, Disk 2, . . . Disk n-1, Disk n</strong></td>
<td>Critical disks are dual ported between HSJ pairs by shared SCSI buses. <strong>Rationale:</strong> Either HSJ can fail and the other HSJ will assume control of the disks that the failed HSJ was controlling.</td>
</tr>
<tr>
<td><strong>Shadow Set 1 through Shadow Set n</strong></td>
<td>Essential disks are shadowed by another disk that is connected on a different shared SCSI. <strong>Rationale:</strong> A disk, or the SCSI bus to which it is connected, or both, can fail and the other shadow set member will still be available. When both disks are available, their combined READ I/O-per-second capacity and READ data bandwidth capacity is available to the cluster.</td>
</tr>
</tbody>
</table>
9.5 Configuration 3

9.5.2 Advantages
Configuration 3 offers the same individual component advantages as configuration 2, plus:

- Both CIs remain usable in the event of localized damage to a CI path.
- Same cost as configuration 2 with better availability.

9.5.3 Disadvantages
Configuration 3 has the following disadvantages:

- Host CI adapter failure will not cause disks to automatically fail over to an HSJ that still has full host connectivity.
  
  If a host CI adapter fails and if MSCP serving is enabled, the other OpenVMS system will begin serving the unreachable HSJ's disks to the host with the failed adapter.

- Damage to star coupler or associated cables likely to affect the same path of both CIs.

- Damage affecting path n of both CIs can halve the usable bandwidth of both CIs.

- Physical damage to the StorageWorks cabinet could render the cluster unusable.

9.5.4 Key Availability and Performance Strategies
Configuration 3 provides all the strategies of configuration 2 except for physical separation of CIs. The major advantage over configuration 2 are the path-specific star coupler cabinets. They provide physical isolation of the path A cables and the path A hub from the path B cables and the path B hub.

9.6 Configuration 4
The availability of a CI configuration can be further improved by physically separating shadow set members and their HSJ controllers. This significantly reduces the probability of a mechanical accident or other localized damage that could destroy both members of a shadow set. This configuration is shown in Figure 9–4.
Figure 9–4 Redundant Components, Path-Separated Star Couplers, and Duplicate StorageWorks Cabinets (Configuration 4)

Configuration 4 is similar to configuration 3 except that the shadow set members and their HSJ controllers are mounted in separate StorageWorks cabinets that are located some distance apart.

The StorageWorks cabinets, path-specific star coupler cabinets, and associated path cables should be separated as much as possible. For example, the StorageWorks cabinets and the star coupler cabinets could be installed on opposite sides of a computer room. The CI cables should be routed so that path A and path B cables follow different paths.

**Note**

The separate StorageWorks cabinets technique illustrated in configuration 4 (Figure 9–4) can also be applied to configuration 1 (Figure 9–1) and configuration 2 (Figure 9–2).
9.6 Configuration 4

9.6.1 Components

The CI OpenVMS Cluster configuration shown in Figure 9–4 has the following components:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host 1, Host 2</td>
<td>Dual CI capable OpenVMS Alpha or VAX hosts. &lt;br&gt; <strong>Rationale:</strong> Either host can fail and the system can continue to run. The full performance of both hosts is available for application use under normal conditions.</td>
</tr>
<tr>
<td>CI 1-1, CI 1-2, CI 2-1, CI 2-2</td>
<td>Dual CI adapters on each host. Adapter CI 1-n is Host 1’s CI adapter connected to CI n, and so on. &lt;br&gt; <strong>Rationale:</strong> Either of a host’s CI adapters can fail and the host will retain CI connectivity to the other host and the HSJ storage controllers. Each CI adapter on a host is connected to a different star coupler. In the absence of failures, the full data bandwidth and I/O-per-second capacity of both CI adapters are available to the host.</td>
</tr>
<tr>
<td>Star Coupler A (Path A Hubs), Star Coupler B (Path B Hubs)</td>
<td>Two CI star couplers, each comprising two independent path hub sections. Star Coupler A’s path hubs are connected to the path A cables for both CIs, and Star Coupler B’s path hubs are connected to the path B cables for both CIs. &lt;br&gt; <strong>Rationale:</strong> Mechanical or other localized damage to a star coupler or an attached cable would probably not affect the other CI paths. The other paths and star coupler would continue to provide full connectivity for both CIs. Loss of a path affects the bandwidth available to the storage controllers and host adapters that are connected to the failed path. When all paths are available, the combined bandwidth of both CIs is usable.</td>
</tr>
<tr>
<td>Path A CI cables, Path B CI cables</td>
<td>Each path’s hub is connected to the CI host adapters and HSJ storage controllers by a transmit/receive cable pair per path. The path A cables of both CIs are routed together, but their routing differs from the routing of the path B cables.</td>
</tr>
<tr>
<td>HSJ 1, HSJ 2</td>
<td>Dual HSJ storage controllers, each in a separate StorageWorks cabinet. Data is replicated across StorageWorks cabinets using Volume Shadowing for DIGITAL OpenVMS. &lt;br&gt; <strong>Rationale:</strong> A StorageWorks cabinet can be destroyed, or one storage controller can fail, and the remaining controller located in the other StorageWorks cabinet can control shadow copies of all disks. When both controllers are available, each can be assigned to serve a subset of the disks. Volume shadowing will distribute READ I/Os across the HSJs. Thus, both controllers can contribute their I/O-per-second and bandwidth capacity to the cluster.</td>
</tr>
<tr>
<td>SCSI 1, SCSI 2</td>
<td>Private SCSI buses connected to an HSJ. &lt;br&gt; <strong>Rationale:</strong> Provide host access to each shadow set member.</td>
</tr>
<tr>
<td>Shadow Set</td>
<td>Essential disks are shadowed between HSJ pairs using volume shadowing. Each HSJ and its disks are in a StorageWorks cabinet that is physically separated from the other StorageWorks cabinet. &lt;br&gt; <strong>Rationale:</strong> An entire StorageWorks cabinet can be destroyed, or a disk, the SCSI bus, or the HSJ to which it is connected can fail, and the other shadow set member will still be available. When both disks are available, they can each provide their READ I/O per second capacity and READ data bandwidth capacity to the cluster.</td>
</tr>
</tbody>
</table>
9.6.2 Advantages
Configuration 4 offers most of the individual component advantages of configuration 3, plus:

- Physical damage to one StorageWorks cabinet is not likely to disable the cluster.
- Disk failover to another HSJ is not a problem.

9.6.3 Disadvantages
Configuration 4 has the following disadvantages:

- Does not have redundant paths to each disk.
- Write I/Os to shadow sets use twice the CI bandwidth of other alternatives.
- Higher cost than configuration 2 and configuration 3.

9.6.4 Key Availability and Performance Strategies
Configuration 4 (Figure 9-4) provides all of the strategies of configuration 3. It also provides shadow set members that are in physically separate StorageWorks cabinets.

9.7 Summary
All four configurations illustrate how to obtain both availability and performance by:

- Adding redundant components
- Dual-porting critical disks
- Shadowing essential disks

An advanced technique, separating the CI path A and path B cables and associated hubs, is used in configuration 3 and configuration 4. This technique increases availability and maintains performance with no additional hardware. Configuration 4 provides even greater availability without compromising performance by physically separating shadow set members and their HSJ controllers.

Using these configurations as a guide, you can select the techniques that are appropriate for your computing needs and adapt your environment as conditions change. The techniques illustrated in these configurations can be scaled for larger CI configurations.
This chapter explains how to maximize scalability in many different kinds of OpenVMS Clusters.

10.1 What Is Scalability?

Scalability is the ability to expand an OpenVMS Cluster system in any system, storage, and interconnect dimension and at the same time fully use the initial configuration equipment. Your OpenVMS Cluster system can grow in many dimensions, as shown in Figure 10-1. Each dimension also enables your applications to expand.

Figure 10–1 OpenVMS Cluster Growth Dimensions

10.1.1 Scalable Dimensions

Table 10–1 describes the growth dimensions for systems, storage, and interconnects in OpenVMS Clusters.
Configuring OpenVMS Clusters for Scalability

10.1 What Is Scalability?

                 Shadowing disks across controllers.  
                 Shadowing disks across systems. |
| I/O            | Adding solid-state or DECramp disks to a cluster.  
                 Adding disks and controllers with caches to a cluster.  
                 Adding RAID disks to a cluster. |
| Controller and array | Moving disks and tapes from systems to controllers.  
                           Combining disks and tapes in arrays.  
                           Adding more controllers and arrays to a cluster. |
| **Interconnect**|             |
| LAN            | Adding Ethernet and FDDI segments.  
                 Upgrading from Ethernet to FDDI.  
                 Adding redundant segments and bridging segments. |
| CI, DSSI, Fibre Channel, SCSI, and MEMORY CHANNEL | Adding CI, DSSI, Fibre Channel, SCSI, and MEMORY CHANNEL interconnects to a cluster or adding redundant interconnects to a cluster. |
| I/O            | Adding faster interconnects for capacity.  
                 Adding redundant interconnects for capacity and availability. |
| Distance       | Expanding a cluster inside a room or a building.  
                 Expanding a cluster across a town or several buildings.  
                 Expanding a cluster between two sites (spanning 40 km). |

The ability to add to the components listed in Table 10–1 in any way that you choose is an important feature that OpenVMS Clusters provide. You can add hardware and software in a wide variety of combinations by carefully following the suggestions and guidelines offered in this chapter and in the products' documentation and DIGITAL Systems and Options Catalog. When you choose to expand your OpenVMS Cluster in a specific dimension, be aware of the advantages and tradeoffs with regard to the other dimensions. Table 10–2 describes strategies that promote OpenVMS Cluster scalability. Understanding these scalability strategies can help you maintain a higher level of performance and availability as your OpenVMS Cluster grows.
10.2 Strategies for Configuring a Highly Scalable OpenVMS Cluster

The hardware that you choose and the way that you configure it has a significant impact on the scalability of your OpenVMS Cluster. This section presents strategies for designing an OpenVMS Cluster configuration that promotes scalability.

10.2.1 Scalability Strategies

Table 10–2 lists strategies in order of importance that ensure scalability. This chapter contains many figures that show how these strategies are implemented.

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capacity planning</td>
<td>Running a system above 80% capacity (near performance saturation) limits the amount of future growth possible. Understand whether your business and applications will grow. Try to anticipate future requirements for processor, memory, and I/O.</td>
</tr>
<tr>
<td>Shared, direct access to all storage</td>
<td>The ability to scale compute and I/O performance is heavily dependent on whether all of the systems have shared, direct access to all storage. The CI and DSSI OpenVMS Cluster illustrations that follow show many examples of shared, direct access to storage, with no MSCP overhead.</td>
</tr>
<tr>
<td>Limit node count to between 3 and 16</td>
<td>Smaller OpenVMS Clusters are simpler to manage and tune for performance and require less OpenVMS Cluster communication overhead than do large OpenVMS Clusters. You can limit node count by upgrading to a more powerful processor and by taking advantage of OpenVMS SMP capability. If your server is becoming a compute bottleneck because it is overloaded, consider whether your application can be split across nodes. If so, add a node; if not, add a processor (SMP).</td>
</tr>
<tr>
<td>Remove system bottlenecks</td>
<td>To maximize the capacity of any OpenVMS Cluster function, consider the hardware and software components required to complete the function. Any component that is a bottleneck may prevent other components from achieving their full potential. Identifying bottlenecks and reducing their effects increases the capacity of an OpenVMS Cluster.</td>
</tr>
<tr>
<td>Enable the MSCP server</td>
<td>The MSCP server enables you to add satellites to your OpenVMS Cluster so that all nodes can share access to all storage. In addition, the MSCP server provides failover for access to shared storage when an interconnect fails.</td>
</tr>
<tr>
<td>Reduce interdependencies and simplify configurations</td>
<td>An OpenVMS Cluster system with one system disk is completely dependent on that disk for the OpenVMS Cluster to continue. If the disk, the node serving the disk, or the interconnects between nodes fail, the entire OpenVMS Cluster system may fail.</td>
</tr>
<tr>
<td>Ensure sufficient serving resources</td>
<td>If a small disk server has to serve a large number disks to many satellites, the capacity of the entire OpenVMS Cluster is limited. Do not overload a server because it will become a bottleneck and will be unable to handle failover recovery effectively.</td>
</tr>
<tr>
<td>Configure resources and consumers close to each other</td>
<td>Place servers (resources) and satellites (consumers) close to each other. If you need to increase the number of nodes in your OpenVMS Cluster, consider dividing it. See Section 11.2.4 for more information.</td>
</tr>
</tbody>
</table>

10.3 Scalability in CI OpenVMS Clusters

Each CI star coupler can have up to 32 nodes attached; 16 can be systems and the rest can be storage controllers and storage. Figure 10–2, Figure 10–3, and Figure 10–4 show a progression from a two-node CI OpenVMS Cluster to a seven-node CI OpenVMS Cluster.

10.3.1 Two-Node CI OpenVMS Cluster

In Figure 10–2, two nodes have shared, direct access to storage that includes a quorum disk. The VAX and Alpha systems each have their own system disks.

Figure 10–2 Two-Node CI OpenVMS Cluster
The advantages and disadvantages of the configuration shown in Figure 10–2 include:

**Advantages**
- All nodes have shared, direct access to all storage.
- As the nodes and storage in this configuration grow, all nodes can still have shared, direct access to storage.
- The MSCP server is enabled for failover to the LAN interconnect in case the CI fails. Enabling the MSCP server also allows you to add satellites.
- This configuration has the lowest cost of the CI configurations shown in this section.

**Disadvantage**
- The single HSJ/HSC is a potential bottleneck and single point of failure.

An increased need for more storage or processing resources could lead to an OpenVMS Cluster configuration like the one shown in Figure 10–3.

### 10.3.2 Three-Node CI OpenVMS Cluster

In Figure 10–3, three nodes are connected to two HSC controllers by the CI interconnects. The critical system disk is dual ported and shadowed.
The advantages and disadvantages of the configuration shown in Figure 10–3 include:

**Advantages**

- All nodes have shared, direct access to all storage.
- As the nodes and storage in this configuration grow, all nodes can still have shared, direct access to storage.
- The MSCP server is enabled for failover to the LAN interconnect, in case the CI fails. Enabling the MSCP server also allows you to add satellites.
- Volume shadowed, dual-ported disks increase data availability.

**Disadvantage**

- The HSJs/HSCs are potential bottlenecks.

If the I/O activity exceeds the capacity of the CI interconnect, this could lead to an OpenVMS Cluster configuration like the one shown in Figure 10–4.
10.3.3 Seven-Node CI OpenVMS Cluster

In Figure 10–4, seven nodes each have a direct connection to two star couplers and to all storage.

Figure 10–4 Seven-Node CI OpenVMS Cluster

The advantages and disadvantages of the configuration shown in Figure 10–4 include:
10.3 Scalability in CI OpenVMS Clusters

Advantages
- All nodes have shared, direct access to all storage.
- This configuration has more than double the storage, processing, and CI interconnect capacity than a configuration like the one shown in Figure 10–3.
- Two CI interconnects between processors and storage provide twice the communication performance of one path.
- Volume shadowed, dual-ported disks increase data availability.

Disadvantage
- This configuration is complex and requires experienced personnel to configure, tune, and manage it properly.

10.3.4 Guidelines for CI OpenVMS Clusters

The following guidelines can help you configure your CI OpenVMS Cluster:
- Every system should have shared, direct access to all storage.
- In a CI OpenVMS Cluster larger than four nodes, use a second system disk for increased system performance.

Reference: For more information on system disks, see Section 11.2.

- Enable your systems, interconnects, and storage to work to their full capacity by eliminating bottlenecks. If any of these components is not able to handle the I/O capacity, none of the other components will work at its best. Ensure that the sum of all the I/O on your nodes is less than or equal to your CI capacity and to your storage capacity. In calculating the sum of the I/O on your nodes, factor in 5–10% extra for lock manager internode communications.

In general, use the following rules of thumb:
- The sum of all the I/Os on your nodes plus internode communications should be less than or equal to the sum of your CI capacity.
- Your CI capacity should be less than or equal to the sum of your storage capacity.

10.3.5 Guidelines for Volume Shadowing in CI OpenVMS Clusters

Volume shadowing is intended to enhance availability, not performance. However, the following volume shadowing strategies enable you to utilize availability features while also maximizing I/O capacity. These examples show CI configurations, but they apply to DSSI and SCSI configurations, as well.
Figure 10–5 shows two nodes connected to an HSJ, with a two-member shadow set.

The disadvantage of this strategy is that the controller is a single point of failure. The configuration in Figure 10–6 shows examples of shadowing across controllers, which prevents one controller from being a single point of failure. Shadowing across HSJ and HSC controllers provides optimal scalability and availability within an OpenVMS Cluster system.
As Figure 10–6 shows, shadowing across controllers has three variations:

- **Strategy A** shows each volume in the shadow set attached to separate controllers. This configuration is not optimal because each volume is not attached to each controller.

- **Strategy B** shows dual-ported devices that have two paths to the volumes through separate controllers. This strategy is an optimal variation because two HSC controllers have direct access to a single storage device.
10.3 Scalability in CI OpenVMS Clusters

- Strategy C shows HSJ controllers shadowed across SCSI buses. It also is an optimal variation because two HSJ controllers have direct access to a single storage device.

Figure 10–7 shows an example of shadowing across nodes.

**Figure 10–7  Volume Shadowing Across Nodes**

As Figure 10–7 shows, shadowing across nodes provides the advantage of flexibility in distance. However, it requires MSCP server overhead for write I/Os. In addition, the failure of one of the nodes and its subsequent return to the OpenVMS Cluster will cause a copy operation.

If you have multiple volumes, shadowing inside a controller and shadowing across controllers are more effective than shadowing across nodes.

**Reference:** See Volume Shadowing for OpenVMS for more information.

10.4 Scalability in DSSI OpenVMS Clusters

Each DSSI interconnect can have up to eight nodes attached; four can be systems and the rest can be storage devices. Figure 10–8, Figure 10–9, and Figure 10–10 show a progression from a two-node DSSI OpenVMS Cluster to a four-node DSSI OpenVMS Cluster.

10.4.1 Two-Node DSSI OpenVMS Cluster

In Figure 10–8, two nodes are connected to four disks by a common DSSI interconnect.
The advantages and disadvantages of the configuration shown in Figure 10–8 include:

**Advantages**
- Both nodes have shared, direct access to all storage.
- The Ethernet LAN ensures failover capability if the DSSI interconnect fails.

**Disadvantages**
- The amount of storage that is directly accessible to all nodes is limited.
- A single DSSI interconnect can become a single point of failure.

If the OpenVMS Cluster in Figure 10–8 required more processing power, more storage, and better redundancy, this could lead to a configuration like the one shown in Figure 10–9.

### 10.4.2 Four-Node DSSI OpenVMS Cluster with Shared Access

In Figure 10–9, four nodes have shared, direct access to eight disks through two DSSI interconnects. Two of the disks are shadowed across DSSI interconnects.
The advantages and disadvantages of the configuration shown in Figure 10–9 include:

**Advantages**
- All nodes have shared, direct access to all storage.
- The Ethernet LAN ensures failover capability if the DSSI interconnect fails.
- Shadowing across DSSI interconnects provides increased performance and availability.

**Disadvantage**
- The amount of storage that is directly accessible to all nodes is limited.

If the configuration in Figure 10–9 required more storage, this could lead to a configuration like the one shown in Figure 10–10.

### 10.4.3 Four-Node DSSI OpenVMS Cluster with Some Nonshared Access

Figure 10–10 shows an OpenVMS Cluster with 4 nodes and 10 disks. This model differs from Figure 10–8 and Figure 10–9 in that some of the nodes do not have shared, direct access to some of the disks, thus requiring these disks to MSCP served. For the best performance, place your highest-priority data on disks that are directly connected by common DSSI interconnects to your nodes. Volume shadowing across common DSSI interconnects provides the highest availability and may increase read performance.
The advantages and disadvantages of the configuration shown in Figure 10–10 include:

**Advantages**
- All nodes have shared, direct access to most of the storage.
- The MSCP server is enabled to allow failover to the alternate DSSI interconnect if one of the DSSI interconnects fails.
- Shadowing across DSSI interconnects provides increased performance and availability.
- The SCSI storage connected through the HSZ controllers provides good performance and scalability.

**Disadvantages**
- The amount of storage that is directly accessible to all nodes is limited.
- Shadow set 2 requires MSCP serving to coordinate shadowing activity.
- Some nodes do not have direct access to storage. For example, Alpha 2 and Alpha 4 do not have direct access to disks connected to Alpha 1 and Alpha 3.
10.5 Scalability in MEMORY CHANNEL OpenVMS Clusters

Each MEMORY CHANNEL (MC) interconnect can have up to four nodes attached to each MEMORY CHANNEL hub. For two-hub configurations, each node must have two PCI adapters, and each adapter must be attached to a different hub. In a two-node configuration, no hub is required because one of the PCI adapters serves as a virtual hub.

Figure 10–11, Figure 10–12, and Figure 10–13 show a progression from a two-node MEMORY CHANNEL cluster to a four-node MEMORY CHANNEL cluster.

Reference: For additional configuration information and a more detailed technical summary of how MEMORY CHANNEL works, see Appendix B.

10.5.1 Two-Node MEMORY CHANNEL Cluster

In Figure 10–11, two nodes are connected by a MEMORY CHANNEL interconnect, a LAN (Ethernet, FDDI, or ATM) interconnect, and a Fibre Channel interconnect.

The advantages and disadvantages of the configuration shown in Figure 10–11 include:

Advantages

- Both nodes have shared, direct access to all storage.
- The Ethernet/FDDI/ATM interconnect enables failover if the MEMORY CHANNEL interconnect fails.
- The limit of two MEMORY CHANNEL nodes means that no hub is required; one PCI adapter serves as a virtual hub.
Disadvantages

- The amount of storage that is directly accessible to all nodes is limited.
- A single SCSI interconnect or HSZ controller can become a single point of failure.

If the OpenVMS Cluster in Figure 10–11 required more processing power and better redundancy, this could lead to a configuration like the one shown in Figure 10–12.

### 10.5.2 Three-Node MEMORY CHANNEL Cluster

In Figure 10–12, three nodes are connected by a high-speed MEMORY CHANNEL interconnect, as well as by a LAN (Ethernet, FDDI, or ATM) interconnect. These nodes also have shared, direct access to storage through the Fibre Channel interconnect.

The advantages and disadvantages of the configuration shown in Figure 10–12 include:

**Advantages**

- All nodes have shared, direct access to storage.
- The Ethernet/FDDI/ATM interconnect enables failover if the MEMORY CHANNEL interconnect fails.
- The addition of a MEMORY CHANNEL hub increases the limit on the number of nodes to a total of four.

**Disadvantage**

- The amount of storage that is directly accessible to all nodes is limited.

If the configuration in Figure 10–12 required more storage, this could lead to a configuration like the one shown in Figure 10–13.
10.5.3 Four-Node MEMORY CHANNEL OpenVMS Cluster

Figure 10–13, each node is connected by a MEMORY CHANNEL interconnect as well as by a CI interconnect.

The advantages and disadvantages of the configuration shown in Figure 10–13 include:

**Advantages**

- All nodes have shared, direct access to all of the storage.
- This configuration has more than double the storage and processing capacity as the one shown in Figure 10–12.
- If the MEMORY CHANNEL interconnect fails, the CI can take over internode communication.
- The CIPCA adapters on two of the nodes enable the addition of Alpha systems to a CI cluster that formerly comprised VAX (CIXCD-based) systems.
- Multiple CIs between processors and storage provide twice the performance of one path. Bandwidth further increases because MEMORY CHANNEL offloads internode traffic from the CI, enabling the CI to be devoted only to storage traffic. This improves the performance of the entire cluster.
10.5 Scalability in MEMORY CHANNEL OpenVMS Clusters

- Volume shadowed, dual-ported disks increase data availability.

**Disadvantage**
- This configuration is complex and requires the care of an experienced system manager.

10.6 Scalability in SCSI OpenVMS Clusters

SCSI-based OpenVMS Clusters allow commodity-priced storage devices to be used directly in OpenVMS Clusters. Using a SCSI interconnect in an OpenVMS Cluster offers you variations in distance, price, and performance capacity. This SCSI clustering capability is an ideal starting point when configuring a low-end, affordable cluster solution. SCSI clusters can range from desktop to desktop to departmental and larger configurations.

Note the following general limitations when using the SCSI interconnect:

- Because the SCSI interconnect handles only storage traffic, it must always be paired with another interconnect for node-to-node traffic. In the figures shown in this section, MEMORY CHANNEL is the alternate interconnect; but CI, DSSI, Ethernet, and FDDI could also be used.

- Total SCSI cable lengths must take into account the system's internal cable length. For example, an AlphaServer 1000 rackmount uses 1.6 m of internal cable to connect the internal adapter to the external connector. Two AlphaServer 1000s joined by a 2 m SCSI cable would use 1.6 m within each system, resulting in a total SCSI bus length of 5.2 m.

**Reference:** For more information about internal SCSI cable lengths as well as highly detailed information about clustering SCSI devices, see Appendix A.

The figures in this section show a progression from a two-node SCSI configuration with modest storage to a four-node SCSI hub configuration with maximum storage and further expansion capability.

10.6.1 Two-Node Fast-Wide SCSI Cluster

In Figure 10–14, two nodes are connected by a 25-m, fast-wide differential (FWD) SCSI bus, with MEMORY CHANNEL (or any) interconnect for internode traffic. The BA356 storage cabinet contains a power supply, a DWZZB single-ended to differential converter, and six disk drives. This configuration can have either narrow or wide disks.
The advantages and disadvantages of the configuration shown in Figure 10–14 include:

**Advantages**

- Low cost SCSI storage is shared by two nodes.
- With the BA356 cabinet, you can use a narrow (8 bit) or wide (16 bit) SCSI bus.
- The DWZZB converts single-ended signals to differential.
- The fast-wide SCSI interconnect provides 20 MB/s performance.
- MEMORY CHANNEL handles internode traffic.
- The differential SCSI bus can be 25 m.

**Disadvantage**

- Somewhat limited storage capability.

If the configuration in Figure 10–14 required even more storage, this could lead to a configuration like the one shown in Figure 10–15.

### 10.6.2 Two-Node Fast-Wide SCSI Cluster with HSZ Storage

In Figure 10–15, two nodes are connected by a 25-m, fast-wide differential (FWD) SCSI bus, with MEMORY CHANNEL (or any) interconnect for internode traffic. Multiple storage shelves are within the HSZ controller.
The advantages and disadvantages of the configuration shown in Figure 10–15 include:

**Advantages**

- Costs slightly more than the configuration shown in Figure 10–14, but offers significantly more storage. (The HSZ controller enables you to add more storage.)
- Cache in the HSZ, which also provides RAID 0, 1, and 5 technologies. The HSZ is a differential device; no converter is needed.
- MEMORY CHANNEL handles internode traffic.
- The FWD bus provides 20 MB/s throughput.
- Includes a 25 m differential SCSI bus.

**Disadvantage**

- This configuration is more expensive than the one shown in Figure 10–14.

### 10.6.3 Three-Node Fast-Wide SCSI Cluster

In Figure 10–16, three nodes are connected by two 25-m, fast-wide (FWD) SCSI interconnects. Multiple storage shelves are contained in each HSZ controller, and more storage is contained in the BA356 at the top of the figure.
The advantages and disadvantages of the configuration shown in Figure 10–16 include:

**Advantages**
- Combines the advantages of the configurations shown in Figure 10–14 and Figure 10–15:
  - Significant (25 m) bus distance and scalability.
  - Includes cache in the HSZ, which also provides RAID 0, 1, and 5 technologies. The HSZ contains multiple storage shelves.
  - FWD bus provides 20 MB/s throughput.
  - With the BA356 cabinet, you can use narrow (8 bit) or wide (16 bit) SCSI bus.

**Disadvantage**
- This configuration is more expensive than those shown in previous figures.
10.6.4 Four-Node Ultra SCSI Hub Configuration

Figure 10–17 shows four nodes connected by a SCSI hub. The SCSI hub obtains power and cooling from the storage cabinet, such as the BA356. The SCSI hub does not connect to the SCSI bus of the storage cabinet.

The advantages and disadvantages of the configuration shown in Figure 10–17 include:

**Advantages**

- Provides significantly more bus distance and scalability than the configuration shown in Figure 10–15.
- The SCSI hub provides fair arbitration on the SCSI bus. This provides more uniform, predictable system behavior. Four CPUs are allowed only when fair arbitration is enabled.
- Up to two dual HSZ controllers can be daisy-chained to the storage port of the hub.
10.6 Scalability in SCSI OpenVMS Clusters

- Two power supplies in the BA356 (one for backup).
- Cache in the HSZs, which also provides RAID 0, 1, and 5 technologies.
- Ultra SCSI bus provides 40 MB/s throughput.

Disadvantage

- You cannot add CPUs to this configuration by daisy-chaining a SCSI interconnect from a CPU or HSZ to another CPU.
- This configuration is more expensive than those shown in Figure 10–14 and Figure 10–15.
- Only HSZ storage can be connected. You cannot attach a storage shelf with disk drives directly to the SCSI hub.

10.7 Scalability in OpenVMS Clusters with Satellites

The number of satellites in an OpenVMS Cluster and the amount of storage that is MSCP served determine the need for the quantity and capacity of the servers. Satellites are systems that do not have direct access to a system disk and other OpenVMS Cluster storage. Satellites are usually workstations, but they can be any OpenVMS Cluster node that is served storage by other nodes in the OpenVMS Cluster.

Each Ethernet LAN segment should have only 10 to 20 satellite nodes attached. Figure 10-18, Figure 10-19, Figure 10-20, and Figure 10-21 show a progression from a 6-satellite LAN to a 45-satellite LAN.

10.7.1 Six-Satellite OpenVMS Cluster

In Figure 10-18, six satellites and a boot server are connected by Ethernet.

Figure 10–18 Six-Satellite LAN OpenVMS Cluster
The advantages and disadvantages of the configuration shown in Figure 10–18 include:

**Advantages**
- The MSCP server is enabled for adding satellites and allows access to more storage.
- With one system disk, system management is relatively simple.

**Reference:** For information about managing system disks, see Section 11.2.

**Disadvantage**
- The Ethernet is a potential bottleneck and a single point of failure.

If the boot server in Figure 10–18 became a bottleneck, a configuration like the one shown in Figure 10–19 would be required.

### 10.7.2 Six-Satellite OpenVMS Cluster with Two Boot Nodes

Figure 10–19 shows six satellites and two boot servers connected by Ethernet. Boot server 1 and boot server 2 perform MSCP server dynamic load balancing: they arbitrate and share the work load between them and if one node stops functioning, the other takes over. MSCP dynamic load balancing requires shared access to storage.

The advantages and disadvantages of the configuration shown in Figure 10–19 include:

**Advantages**
- The MSCP server is enabled for adding satellites and allows access to more storage.
- Two boot servers perform MSCP dynamic load balancing.

**Disadvantage**
- The Ethernet is a potential bottleneck and a single point of failure.

If the LAN in Figure 10–19 became an OpenVMS Cluster bottleneck, this could lead to a configuration like the one shown in Figure 10–20.
10.7 Scalability in OpenVMS Clusters with Satellites

10.7.3 Twelve-Satellite LAN OpenVMS Cluster with Two LAN Segments

Figure 10–20 shows 12 satellites and 2 boot servers connected by two Ethernet segments. These two Ethernet segments are also joined by a LAN bridge. Because each satellite has dual paths to storage, this configuration also features MSCP dynamic load balancing.

Figure 10–20 Twelve-Satellite OpenVMS Cluster with Two LAN Segments

The advantages and disadvantages of the configuration shown in Figure 10–20 include:

**Advantages**

- The MSCP server is enabled for adding satellites and allows access to more storage.
- Two boot servers perform MSCP dynamic load balancing.
  
  From the perspective of a satellite on the Ethernet LAN, the dual paths to the Alpha and VAX nodes create the advantage of MSCP load balancing.
- Two LAN segments provide twice the amount of LAN capacity.

**Disadvantages**

- This OpenVMS Cluster configuration is limited by the number of satellites that it can support.
- The single HSJ controller is a potential bottleneck and a single point of failure.
If the OpenVMS Cluster in Figure 10–20 needed to grow beyond its current limits, this could lead to a configuration like the one shown in Figure 10–21.

10.7.4 Forty-Five Satellite OpenVMS Cluster with FDDI Ring

Figure 10–21 shows a large, 51-node OpenVMS Cluster that includes 45 satellite nodes. The three boot servers, Alpha 1, Alpha 2, and Alpha 3, share three disks: a common disk, a page and swap disk, and a system disk. The FDDI ring has three LAN segments attached. Each segment has 15 workstation satellites as well as its own boot node.

The advantages and disadvantages of the configuration shown in Figure 10–21 include:

**Advantages**

- Decreased boot time, especially for an OpenVMS Cluster with such a high node count.

  **Reference:** For information about booting an OpenVMS Cluster like the one in Figure 10–21 see Section 11.2.4.

- The MSCP server is enabled for satellites to access more storage.
• Each boot server has its own page and swap disk, which reduces I/O activity on the system disks.

• All of the environment files for the entire OpenVMS Cluster are on the common disk. This frees the satellite boot servers to serve only root information to the satellites.

**Reference:** For more information about common disks and page and swap disks, see Section 11.2.

• The FDDI ring provides 10 times the capacity of one Ethernet interconnect.

**Disadvantages**

• The satellite boot servers on the Ethernet LAN segments can boot satellites only on their own segments.

### 10.7.5 High-Powered Workstation OpenVMS Cluster

Figure 10–22 shows an OpenVMS Cluster configuration that provides high performance and high availability on the FDDI ring.
In Figure 10–22, several Alpha workstations, each with its own system disk, are connected to the FDDI ring. Putting Alpha workstations on the FDDI provides high performance because each workstation has direct access to its system disk. In addition, the FDDI bandwidth is higher than that of the Ethernet. Because Alpha workstations have FDDI adapters, putting these workstations on an FDDI is a useful alternative for critical workstation requirements. FDDI is 10 times faster than Ethernet, and Alpha workstations have processing capacity that can take advantage of FDDI’s speed.
10.7.6 Guidelines for OpenVMS Clusters with Satellites

The following are guidelines for setting up an OpenVMS Cluster with satellites:

- Extra memory is required for satellites of large LAN configurations because each node must maintain a connection to every other node.
- Place only 10 to 20 satellites on each LAN segment.
- Maximize resources with MSCP dynamic load balancing, as shown in Figure 10–19 and Figure 10–20.
- Keep the number of nodes that require MSCP serving minimal for good performance.

**Reference:** See Section 10.8.1 for more information about MSCP overhead.

- To save time, ensure that the booting sequence is efficient, particularly when the OpenVMS Cluster is large or has multiple segments. See Section 11.2.4 for more information about how to reduce LAN and system disk activity and how to boot separate groups of nodes in sequence.
- Use two or more LAN adapters per host (up to four adapters are supported for OpenVMS Cluster communications), and connect to independent LAN paths. This enables simultaneous two-way communication between nodes and allows traffic to multiple nodes to be spread over the available LANs.

10.7.7 Extended LAN Configuration Guidelines

You can use bridges between LAN segments to form an extended LAN (ELAN). This can increase availability, distance, and aggregate bandwidth as compared with a single LAN. However, an ELAN can increase delay and can reduce bandwidth on some paths. Factors such as packet loss, queuing delays, and packet size can also affect ELAN performance. Table 10–3 provides guidelines for ensuring adequate LAN performance when dealing with such factors.

**Table 10–3 ELAN Configuration Guidelines**

<table>
<thead>
<tr>
<th>Factor</th>
<th>Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Propagation delay</td>
<td>The amount of time it takes a packet to traverse the ELAN depends on the distance it travels and the number of times it is relayed from one link to another by a bridge or a station on the FDDI ring. If responsiveness is critical, then you must control these factors. When an FDDI is used for OpenVMS Cluster communications, the ring latency when the FDDI ring is idle should not exceed 400 ms. FDDI packets travel at 5.085 microseconds/km and each station causes an approximate 1-ms delay between receiving and transmitting. You can calculate FDDI latency by using the following algorithm: [ Latency = \text{(distance in km)} \times (5.085 \text{ ms/km}) + (\text{number of stations}) \times (1 \text{ ms/station}) ] For high-performance applications, limit the number of bridges between nodes to two. For situations in which high performance is not required, you can use up to seven bridges between nodes.</td>
</tr>
</tbody>
</table>

(continued on next page)
### Table 10-3 (Cont.) ELAN Configuration Guidelines

<table>
<thead>
<tr>
<th>Factor</th>
<th>Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Queuing delay</strong></td>
<td>Queuing occurs when the instantaneous arrival rate at bridges and host adapters exceeds the service rate. You can control queuing by:</td>
</tr>
<tr>
<td></td>
<td>• Reducing the number of bridges between nodes that communicate frequently.</td>
</tr>
<tr>
<td></td>
<td>• Using only high-performance bridges and adapters.</td>
</tr>
<tr>
<td></td>
<td>• Reducing traffic bursts in the LAN. In some cases, for example, you can tune applications by combining small I/Os so that a single packet</td>
</tr>
<tr>
<td></td>
<td>is produced rather than a burst of small ones.</td>
</tr>
<tr>
<td></td>
<td>• Reducing LAN segment and host processor utilization levels by using faster processors and faster LANs, and by using bridges for traffic</td>
</tr>
<tr>
<td></td>
<td>isolation.</td>
</tr>
<tr>
<td><strong>Packet loss</strong></td>
<td>Packets that are not delivered by the ELAN require retransmission, which wastes network resources, increases delay, and reduces bandwidth.</td>
</tr>
<tr>
<td></td>
<td>Bridges and adapters discard packets when they become congested. You can reduce packet loss by controlling queuing, as previously described.</td>
</tr>
<tr>
<td></td>
<td>Packets are also discarded when they become damaged in transit. You can control this problem by observing LAN hardware configuration</td>
</tr>
<tr>
<td></td>
<td>rules, removing sources of electrical interference, and ensuring that all hardware is operating correctly.</td>
</tr>
<tr>
<td></td>
<td>Packet loss can also be reduced by using VMS Version 5.5–2 or later, which has PEDRIVER congestion control.</td>
</tr>
<tr>
<td></td>
<td>The retransmission timeout rate, which is a symptom of packet loss, must be less than 1 timeout in 1000 transmissions for OpenVMS Cluster</td>
</tr>
<tr>
<td></td>
<td>traffic from one node to another. ELAN paths that are used for high-performance applications should have a significantly lower rate.</td>
</tr>
<tr>
<td></td>
<td>Monitor the occurrence of retransmission timeouts in the OpenVMS Cluster.</td>
</tr>
<tr>
<td><strong>Reference:</strong></td>
<td>For information about monitoring the occurrence of retransmission timeouts, see OpenVMS Cluster Systems.</td>
</tr>
<tr>
<td><strong>Bridge recovery delay</strong></td>
<td>Choose bridges with fast self-test time and adjust bridges for fast automatic reconfiguration.</td>
</tr>
<tr>
<td><strong>Reference:</strong></td>
<td>Refer to OpenVMS Cluster Systems for more information about LAN bridge failover.</td>
</tr>
<tr>
<td><strong>Bandwidth</strong></td>
<td>All LAN paths used for OpenVMS Cluster communication must operate with a nominal bandwidth of at least 10 Mb/s. The average LAN segment</td>
</tr>
<tr>
<td></td>
<td>utilization should not exceed 60% for any 10-second interval.</td>
</tr>
<tr>
<td></td>
<td>Use FDDI exclusively on the communication paths that have the highest performance requirements. Do not put an Ethernet LAN segment</td>
</tr>
<tr>
<td></td>
<td>between two FDDI segments. FDDI bandwidth is significantly greater, and the Ethernet LAN will become a bottleneck. This strategy is</td>
</tr>
<tr>
<td></td>
<td>especially ineffective if a server on one FDDI must serve clients on another FDDI with an Ethernet LAN between them. A more appropriate</td>
</tr>
<tr>
<td></td>
<td>strategy is to put a server on an FDDI and put clients on an Ethernet LAN, as Figure 10–21 shows.</td>
</tr>
<tr>
<td><strong>Traffic isolation</strong></td>
<td>Use bridges to isolate and localize the traffic between nodes that communicate with each other frequently. For example, use bridges to</td>
</tr>
<tr>
<td></td>
<td>separate the OpenVMS Cluster from the rest of the ELAN and to separate nodes within an OpenVMS Cluster that communicate frequently from</td>
</tr>
<tr>
<td></td>
<td>the rest of the OpenVMS Cluster. Provide independent paths through the ELAN between critical systems that have multiple adapters.</td>
</tr>
</tbody>
</table>

(continued on next page)
### 10.7 Scalability in OpenVMS Clusters with Satellites

<table>
<thead>
<tr>
<th>Factor</th>
<th>Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Packet size</td>
<td>You can adjust the NISCS_MAX_PKTSZ system parameter to use the full FDDI packet size. Ensure that the ELAN path supports a data field of at least 4474 bytes end to end. Some failures cause traffic to switch from an ELAN path that supports 4474-byte packets to a path that supports only smaller packets. It is possible to implement automatic detection and recovery from these kinds of failures. This capability requires that the ELAN set the value of the priority field in the FDDI frame-control byte to zero when the packet is delivered on the destination FDDI link. Ethernet-to-FDDI bridges that conform to the IEEE 802.1 bridge specification provide this capability.</td>
</tr>
</tbody>
</table>

### 10.7.8 System Parameters for OpenVMS Clusters

In an OpenVMS Cluster with satellites and servers, specific system parameters can help you manage your OpenVMS Cluster more efficiently. Table 10–4 gives suggested values for these system parameters.

<table>
<thead>
<tr>
<th>System Parameter</th>
<th>Value for Satellites</th>
<th>Value for Servers</th>

**Reference:** For a more in-depth description of these parameters, see OpenVMS Cluster Systems.

### 10.8 Scaling for I/Os

The ability to scale I/Os is an important factor in the growth of your OpenVMS Cluster. Adding more components to your OpenVMS Cluster requires high I/O throughput so that additional components do not create bottlenecks and decrease the performance of the entire OpenVMS Cluster. Many factors can affect I/O throughput:

- Direct access or MSCP served access to storage
- File system technologies, such as Files-11
- Disk technologies, such as magnetic disks, solid-state disks, and DECram
- Read/write ratio
10.8 Scaling for I/Os

- I/O size
- Caches and cache “hit” rate
- “Hot file” management
- RAID striping and host-based striping
- Volume shadowing

These factors can affect I/O scalability either singly or in combination. The following sections explain these factors and suggest ways to maximize I/O throughput and scalability without having to change in your application.

Additional factors that affect I/O throughput are types of interconnects and types of storage subsystems.

Reference: See Chapter 4 for more information about interconnects and Chapter 5 for more information about types of storage subsystems.

10.8.1 MSCP Served Access to Storage

MSCP server capability provides a major benefit to OpenVMS Clusters: it enables communication between nodes and storage that are not directly connected to each other. However, MSCP served I/O does incur overhead. Figure 10–23 is a simplification of how packets require extra handling by the serving system.

In Figure 10–23, an MSCP served packet requires an extra “stop” at another system before reaching its destination. When the MSCP served packet reaches the system associated with the target storage, the packet is handled as if for direct access.

In an OpenVMS Cluster that requires a large amount of MSCP serving, I/O performance is not as efficient and scalability is decreased. The total I/O throughput is approximately 20% less when I/O is MSCP served than when it has direct access. Design your configuration so that a few large nodes are serving many satellites rather than satellites serving their local storage to the entire OpenVMS Cluster.
10.8.2 Disk Technologies

In recent years, the ability of CPUs to process information has far outstripped the ability of I/O subsystems to feed processors with data. The result is an increasing percentage of processor time spent waiting for I/O operations to complete.

Solid-state disks (SSDs), DECram, and RAID level 0 bridge this gap between processing speed and magnetic-disk access speed. Performance of magnetic disks is limited by seek and rotational latencies, while SSDs and DECram use memory, which provides nearly instant access.

RAID level 0 is the technique of spreading (or "striping") a single file across several disk volumes. The objective is to reduce or eliminate a bottleneck at a single disk by partitioning heavily accessed files into stripe sets and storing them on multiple devices. This technique increases parallelism across many disks for a single I/O.

Table 10–5 summarizes disk technologies and their features.

<table>
<thead>
<tr>
<th>Disk Technology</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECram</td>
<td>Highest throughput for small to medium I/O requests.</td>
</tr>
<tr>
<td>RAID level 0</td>
<td>Available on HSJ and HSD controllers.</td>
</tr>
</tbody>
</table>

**Note:** Shared, direct access to a solid-state disk or to DECram is the fastest alternative for scaling I/Os.

10.8.3 Read/Write Ratio

The read/write ratio of your applications is a key factor in scaling I/O to shadow sets. MSCP writes to a shadow set are duplicated on the interconnect.

Therefore, an application that has 100% (100/0) read activity may benefit from volume shadowing because shadowing causes multiple paths to be used for the I/O activity. An application with a 50/50 ratio will cause more interconnect utilization because write activity requires that an I/O be sent to each shadow member. Delays may be caused by the time required to complete the slowest I/O.

To determine I/O read/write ratios, use the DCL command MONITOR IO.

10.8.4 I/O Size

Each I/O packet incurs processor and memory overhead, so grouping I/Os together in one packet decreases overhead for all I/O activity. You can achieve higher throughput if your application is designed to use bigger packets. Smaller packets incur greater overhead.
10.8.5 Caches

Caching is the technique of storing recently or frequently used data in an area where it can be accessed more easily—in memory, in a controller, or in a disk. Caching complements solid-state disks, DECramp, and RAID. Applications automatically benefit from the advantages of caching without any special coding. Caching reduces current and potential I/O bottlenecks within OpenVMS Cluster systems by reducing the number of I/Os between components.

Table 10–6 describes the three types of caching.

<table>
<thead>
<tr>
<th>Caching Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host based</td>
<td>Cache that is resident in the host system’s memory and services I/Os from the host.</td>
</tr>
<tr>
<td>Controller based</td>
<td>Cache that is resident in the storage controller and services data for all hosts.</td>
</tr>
<tr>
<td>Disk</td>
<td>Cache that is resident in a disk.</td>
</tr>
</tbody>
</table>

Host-based disk caching provides different benefits from controller-based and disk-based caching. In host-based disk caching, the cache itself is not shareable among nodes. Controller-based and disk-based caching are shareable because they are located in the controller or disk, either of which is shareable.

10.8.6 Managing “Hot” Files

A “hot” file is a file in your system on which the most activity occurs. Hot files exist because, in many environments, approximately 80% of all I/O goes to 20% of data. This means that, of equal regions on a disk drive, 80% of the data being transferred goes to one place on a disk, as shown in Figure 10–24.

To increase the scalability of I/Os, focus on hot files, which can become a bottleneck if you do not manage them well. The activity in this area is expressed in I/Os, megabytes transferred, and queue depth.

RAID level 0 balances hot-file activity by spreading a single file over multiple disks. This reduces the performance impact of hot files.

Use the following DCL commands to analyze hot-file activity:
- MONITOR IO command—Monitors hot disks.
• MONITOR MSCP command—Monitors MSCP servers.

The MONITOR IO and the MONITOR MSCP commands enable you to find out which disk and which server are hot.

10.8.7 Volume Shadowing

The Volume Shadowing for OpenVMS product ensures that data is available to applications and end users by duplicating data on multiple disks. Although volume shadowing provides data redundancy and high availability, it can affect OpenVMS Cluster I/O on two levels:

<table>
<thead>
<tr>
<th>Factor</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geographic distance</td>
<td>Host-based volume shadowing enables shadowing of any disk volumes in an OpenVMS Cluster system, including those served by MSCP servers. This ability can allow great distances along with MSCP overhead. For example, OpenVMS Cluster systems using FDDI can be located up to 25 miles apart. Both the distance and the MSCP involvement can slow I/O throughput.</td>
</tr>
<tr>
<td>Read/write ratio</td>
<td>Because shadowing writes data to multiple volumes, applications that are write intensive may experience reduced throughput. In contrast, read-intensive applications may experience increased throughput because the shadowing software selects one disk member from which it can retrieve the data most efficiently.</td>
</tr>
</tbody>
</table>
This chapter suggests some key system management strategies that you can use to get the most out of your OpenVMS Cluster. It is not intended to be a comprehensive discussion of the most common OpenVMS Cluster system management practices; see OpenVMS Cluster Systems for that information.

This chapter also assumes that the reader has some familiarity with basic system management concepts, such as system disks, quorum disks, and OpenVMS Cluster transitions.

The following information is contained in this chapter:

- System disk strategies
- Common and multiple environment strategies
- Quorum strategies
- State transition strategies
- Multiple OpenVMS versions in the same OpenVMS Cluster
- Alpha and VAX systems in the same OpenVMS Cluster
- Backup and storage management strategies

11.1 Simple and Complex Configurations

OpenVMS Cluster software makes a system manager’s job easier because many system management tasks need to be done only once. This is especially true if business requirements call for a simple configuration rather than for every feature that an OpenVMS Cluster can provide. The simple configuration is appealing to both new and experienced system managers and is applicable to small OpenVMS Clusters—those with 3 to 7 nodes, 20 to 30 users, and 100 GB of storage.

Reference: See Figure 11–1 for an example of a simple OpenVMS Cluster configuration.

More complex OpenVMS Cluster configurations may require a more sophisticated system management strategy to deliver more availability, scalability, and performance.

Reference: See Figure 11–3 for an example of a complex OpenVMS Cluster configuration.

Choose system management strategies that balance simplicity of system management with the additional management tasks required by more complex OpenVMS Clusters.
11.2 System Disk Strategies

System disks contain system files and environment files. System files are primarily read-only images and command procedures, such as run-time libraries, and are accessed clusterwide. Environment files create specific working environments for users. You can create a common environment by making all environment files accessible clusterwide, or you can create multiple environments by making specific environment files accessible to only certain users or systems.

11.2.1 Single System Disk

System management is easiest for a simple configuration that has a single system disk and a common environment. Most procedures need to be performed only once, and both system files and environment files are located on the same disk. Page and swap files are also located on the system disk.

Figure 11-1 shows an example of a simple OpenVMS Cluster with a single system disk and a common environment.
In Figure 11–1, a simple CI OpenVMS Cluster contains a single, shadowed system disk. This system disk contains system files, environment files, and page and swap files. Because there is one set of environment files, this is a common environment.

Figure 11–2 shows another variation of a simple OpenVMS Cluster with a common environment.
In Figure 11–2, six satellites and one boot server are connected by Ethernet. Each satellite has its own page and swap disk, which saves system disk space and removes the I/O activity of page and swap files from the Ethernet. Removing page and swap files from the system disk improves performance for the OpenVMS Cluster.

Although the single-system-disk configuration works well for many OpenVMS Cluster requirements, multiple system disks can offer several advantages.

11.2.2 Multiple System Disks

OpenVMS Clusters that include both Alpha and VAX systems require multiple system disks: a VAX system disk and an Alpha system disk. Table 11–1 gives some additional reasons (not related to architecture) why a system manager might want more than one system disk in a OpenVMS Cluster.
Table 11–1 Advantages of Multiple System Disks

<table>
<thead>
<tr>
<th>Advantage</th>
<th>Description</th>
</tr>
</thead>
</table>
| Decreased boot times                     | A single system disk can be a bottleneck when booting three or more systems simultaneously. Boot times are highly dependent on:  
  • LAN utilization  
  • Speed of the system disk  
  • Number of disks mounted  
  • Number of applications installed  
  • Proximity of boot node to satellites  
  • Boot node’s processing power  
  • Whether environment files are on the system disk  
  • Whether the system disk is shadowed  
  Volume Shadowing for OpenVMS software can help disk read performance, assuming that environment files that experience high write activity (such as SYSUAF.DAT) are not on the system disk. |
| Increased system and application performance | If your OpenVMS Cluster has many different applications that are in constant use, it may be advantageous to have either a local system disk for every node or a system disk that serves fewer systems. The benefits are shorter image-activation times and fewer files being served over the LAN.  
  Alpha workstations benefit from a local system disk because the powerful Alpha processor does not have to wait as long for system disk access.  
  Reference: See Section 10.7.5 for more information. |
| Reduced LAN utilization                   | More system disks reduce LAN utilization because fewer files are served over the LAN. Isolating LAN segments and their boot servers from unnecessary traffic outside the segments decreases LAN path contention.  
  Reference: See Section 11.2.4 for more information. |
| Increased OpenVMS Cluster availability   | A single system disk can become a single point of failure. Increasing the number of boot servers and system disks increases availability by reducing the OpenVMS Cluster’s dependency on a single resource. |

11.2.3 Multiple System-Disk OpenVMS Cluster

Arranging system disks as shown in Figure 11–3 can reduce booting time and LAN utilization.
Figure 11–3 is an OpenVMS Cluster with multiple system disks:

- One for Alpha 1, Alpha 2, and Alpha 3
- One for each boot server on the LAN segments

The use of multiple system disks in this configuration and the way that the LAN segments are divided enable the booting sequence to be efficient and timely.

11.2.4 Dividing an OpenVMS Cluster System

In the workstation server examples shown in Section 10.7, OpenVMS Cluster reboots after a failure are relatively simple because of the small number of satellites per server. However, reboots in the larger, OpenVMS Cluster configuration shown in Figure 11–3 require careful planning. Dividing this OpenVMS Cluster and arranging the system disks as described in this section can reduce booting time significantly. Dividing the OpenVMS Cluster can
also reduce the satellite utilization of the LAN segment and increase satellite performance.

The disks in this OpenVMS Cluster have specific functions, as described in Table 11–2.

### Table 11–2 How Multiple System Disks Are Used

<table>
<thead>
<tr>
<th>Disk</th>
<th>Contents</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common disk</td>
<td>All environment files for the entire OpenVMS Cluster</td>
<td>Environment files such as SYSUAF.DAT, NETPROXY.DAT, QMANS$MASTER.DAT are accessible to all nodes—including satellites—during booting. This frees the satellite boot servers to serve only system files and root information to the satellites. To create a common environment and increase performance for all system disks, see Section 11.3.</td>
</tr>
<tr>
<td>System disk</td>
<td>System roots for Alpha 1, Alpha 2, and Alpha 3</td>
<td>High performance for server systems. Make this disk as read-only as possible by taking environment files that have write activity off the system disk. The disk can be mounted clusterwide in SYLOGICALS.COM during startup.</td>
</tr>
<tr>
<td>Satellite boot servers' system disks</td>
<td>System files or roots for the satellites</td>
<td>Frees the system disk attached to Alpha 1, Alpha 2, and Alpha 3 from having to serve satellites, and divide total LAN traffic over individual Ethernet segments.</td>
</tr>
<tr>
<td>Page and swap disks</td>
<td>Page and swap files for one or more systems</td>
<td>Reduce I/O activity on the system disks, and free system disk space for applications and system roots.</td>
</tr>
</tbody>
</table>

In a booting sequence for the configuration in Figure 11–3, make sure that nodes Alpha 1, Alpha 2, and Alpha 3 are entirely booted before booting the LAN Ethernet segments so that the files on the common disk are available to the satellites. Enable filtering of the Maintenance Operations Protocol (MOP) on the Ethernet-to-FDDI (10/100) bridges so that the satellites do not try to boot from the system disks for Alpha 1, Alpha 2, and Alpha 3. The order in which to boot this OpenVMS Cluster is:

1. Boot Alpha 1, Alpha 2, and Alpha 3.
2. Boot the satellite boot servers.
3. Boot all satellites.

**Reference:** See Section 10.7.6 for information about extended LANs.

### 11.2.5 Summary: Single Versus Multiple System Disks

Use the information in Table 11–3 to determine whether you need a system disk for the entire OpenVMS Cluster or multiple system disks.
### 11.2 System Disk Strategies

<table>
<thead>
<tr>
<th>Table 11-3: Comparison of Single and Multiple System Disks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Single System Disk</strong></td>
</tr>
<tr>
<td>Node may have to wait longer for access to a file on the system disk.</td>
</tr>
<tr>
<td>Contention for a single resource increases.</td>
</tr>
<tr>
<td>Boot time for satellites increases.</td>
</tr>
<tr>
<td>Only one system disk to manage.</td>
</tr>
<tr>
<td>Less complex system management.</td>
</tr>
<tr>
<td>Lower hardware and software costs.</td>
</tr>
<tr>
<td>Lower cost of system management because less time and experience required to manage a single system disk.</td>
</tr>
</tbody>
</table>

### 11.3 OpenVMS Cluster Environment Strategies

Depending on your processing needs, you can prepare either a common environment, in which all environment files are shared clusterwide, or a multiple environment, in which some files are shared clusterwide and others are accessible only by certain OpenVMS Cluster members.

The following are the most frequently used and manipulated OpenVMS Cluster environment files:

- `SYS$SYSTEM:SYSUAF.DAT`
- `SYS$SYSTEM:NETPROXY.DAT`
- `SYS$SYSTEM:VMSMAIL_PROFILE.DATA`
- `SYS$SYSTEM:NETNODE_REMOTE.DAT`
- `SYS$MANAGER:NETNODE_UPDATE.COM`
- `SYS$SYSTEM:RIGHTSLIST.DAT`
- `SYS$SYSTEM:QMAN$MASTER.DAT`

**Reference:** For more information about managing these files, see *OpenVMS Cluster Systems*.

### 11.3.1 Common Environment

A common OpenVMS Cluster environment is an operating environment that is identical on all nodes in the OpenVMS Cluster. A common environment is easier to manage than multiple environments because you use a common version of each system file. The environment is set up so that:

- All nodes run the same programs, applications, and utilities.
- All users have the same type of accounts, and the same logical names are defined.
- All users can have common access to storage devices and queues.
- All users can log in to any node in the configuration and can work in the same environment as all other users.
The simplest and most inexpensive environment strategy is to have one system disk for the OpenVMS Cluster with all environment files on the same disk, as shown in Figure 11–1. The benefits of this strategy are:

- Software products need to be installed only once.
- All environment files are on the system disk and are easier to locate and manage.
- Booting dependencies are clear.

11.3.2 Putting Environment Files on a Separate, Common Disk

For an OpenVMS Cluster in which every node share the same system disk and environment, most common environment files are located in the SYS$SYSTEM directory.

However, you may want to move environment files to a separate disk so that you can improve OpenVMS Cluster performance. Because the environment files typically experience 80% of the system-disk activity, putting them on a separate disk decreases activity on the system disk. Figure 11–3 shows an example of a separate, common disk.

If you move environment files such as SYSUAF.DAT to a separate, common disk, SYSUAF.DAT will not be located in its default location of SYS$SYSTEM:SYSUAF.DAT.

Reference: See OpenVMS Cluster Systems for procedures to ensure that every node in the OpenVMS Cluster can access SYSUAF.DAT in its new location.

11.3.3 Multiple Environments

Multiple environments can vary from node to node. You can set up an individual node or a subset of nodes to:

- Provide multiple access according to the type of tasks users perform and the resources they use.
- Share a set of resources that are not available on other nodes.
- Perform specialized functions using restricted resources while other processors perform general timesharing work.
- Allow users to work in environments that are specific to the node where they are logged in.

Figure 11–4 shows an example of a multiple environment.
In Figure 11-4, the multiple-environment OpenVMS Cluster consists of two system disks: one for VAX nodes and one for Alpha nodes. The common disk contains environment files for each node or group of nodes. Although many OpenVMS Cluster system managers prefer the simplicity of a single (common) environment, duplicating environment files is necessary for creating multiple environments that do not share resources across every node. Each environment can be tailored to the types of tasks users perform and the resources they use, and the configuration can have many different applications installed.

Each of the four DSSI nodes has its own page and swap disk, offloading the Alpha and VAX system disks on the DSSI interconnect from page and swap activity. All of the disks are shadowed across the DSSI interconnects, which protects the disks if a failure occurs.

11.4 Additional Multiple-Environment Strategies

This section describes additional multiple-environment strategies, such as using multiple SYSUAF.DAT files and multiple queue managers.

11.4.1 Using Multiple SYSUAF.DAT Files

Most OpenVMS Clusters are managed with one user authorization (SYSUAF.DAT) file, but you can use multiple user authorization files to limit access for some users to certain systems. In this scenario, users who need access to all systems also need multiple passwords.

Be careful about security with multiple SYSUAF.DAT files. The OpenVMS VAX and OpenVMS Alpha operating systems do not support multiple security domains.

Reference: See OpenVMS Cluster Systems for the list of fields that need to be the same for a single security domain, including SYSUAF.DAT entries.
11.4 Additional Multiple-Environment Strategies

Because Alpha systems require higher process quotas, system managers often respond by creating multiple SUSUAF.DAT files. This is not an optimal solution. Multiple SUSUAF.DAT files are intended only to vary environments from node to node, not to increase process quotas. To increase process quotas, Compaq recommends that you have one SUSUAF.DAT file and that you use system parameters to override process quotas in the SUSUAF.DAT file with system parameters to control resources for your Alpha systems.

11.4.2 Using Multiple Queue Managers

If the number of batch and print transactions on your OpenVMS Cluster is causing congestion, you can implement multiple queue managers to distribute the batch and print loads between nodes.

Every OpenVMS Cluster has only one QMAN$MASTER.DAT file. Multiple queue managers are defined through multiple *.QMAN$QUEUES and *.QMAN$JOURNAL files. Place each pair of queue manager files on different disks. If the QMAN$MASTER.DAT file has contention problems, place it on a solid-state disk to increase the number of batch and print transactions your OpenVMS Cluster can process. For example, you can create separate queue managers for batch queues and print queues.

Reference: See OpenVMS System Manager’s Manual, Volume 1: Essentials for examples and commands to implement multiple queue managers.

11.5 Quorum Strategies

OpenVMS Cluster systems use a quorum algorithm to ensure synchronized access to storage. The quorum algorithm is a mathematical method for determining whether a majority of OpenVMS Cluster members exists so that they can “vote” on how resources can be shared across an OpenVMS Cluster system. The connection manager, which calculates quorum as a dynamic value, allows processing to occur only if a majority of the OpenVMS Cluster members are functioning.

Quorum votes are contributed by:

- Systems with the parameter VOTES set to a number greater than zero
- A designated disk, called a quorum disk

Each OpenVMS Cluster system can include only one quorum disk. The disk cannot be a member of a shadow set, but it can be the system disk.

The connection manager knows about the quorum disk from “quorum disk watchers,” which are any systems that have a direct, active connection to the quorum disk.

11.5.1 Quorum Strategy Options

At least two systems should have a direct connection to the quorum disk. This ensures that the quorum disk votes are accessible if one of the systems fails.

When you consider quorum strategies, you must decide under what failure circumstances you want the OpenVMS Cluster to continue. Table 11-4 describes four options from which to choose.
11.5 Quorum Strategies

Table 11-4  Quorum Strategies

<table>
<thead>
<tr>
<th>Strategy Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Continue if the majority of the maximum &quot;expected&quot; nodes still remain.</td>
<td>Give every node a vote and do not use a quorum disk. This strategy requires three or more nodes.</td>
</tr>
<tr>
<td>Continue with only one node remaining (of three or more nodes).</td>
<td>This strategy requires a quorum disk. By increasing the quorum disk's votes to one less than the total votes from all systems (and by increasing the value of the EXPECTED_VOTES system parameter by the same amount), you can boot and run the cluster with only one node as a quorum disk watcher. This prevents having to wait until more than half the voting systems are operational before you can start using the OpenVMS Cluster system.</td>
</tr>
<tr>
<td>Continue with only one node remaining (two-node OpenVMS Cluster).</td>
<td>Give each node and the quorum disk a vote. The two-node OpenVMS Cluster is a special case of this alternative. By establishing a quorum disk, you can increase the availability of a two-node OpenVMS Cluster. Such configurations can maintain quorum and continue to operate in the event of failure of either the quorum disk or one node. This requires that both nodes be directly connected to storage (by CI, DSSI, SCSI, or Fibre Channel) for both to be quorum disk watchers.</td>
</tr>
<tr>
<td>Continue with only critical nodes in the OpenVMS Cluster.</td>
<td>Generally, this strategy gives servers votes and gives satellites none. This assumes three or more servers and no quorum disk.</td>
</tr>
</tbody>
</table>

1These strategies are mutually exclusive; choose only one.

Reference: For more information about quorum disk management, see OpenVMS Cluster Systems.

11.6 State Transition Strategies

OpenVMS Cluster state transitions occur when a system joins or leaves an OpenVMS Cluster system and when the OpenVMS Cluster recognizes a quorum-disk state change. The connection manager handles these events to ensure the preservation of data integrity throughout the OpenVMS Cluster.

State transitions should be a concern only if systems are joining or leaving an OpenVMS Cluster system frequently enough to cause disruption.

A state transition's duration and effect on users and applications is determined by the reason for the transition, the configuration, and the applications in use. By managing transitions effectively, system managers can control:

- Detection of failures and how long the transition takes
- Side effects of the transition, such as volume shadowing copy and merge operations

11.6.1 Dealing with State Transitions

The following guidelines describe effective ways of dealing with transitions so that you can minimize the actual transition time as well as the side effects after the transition.

- Be proactive in preventing nodes from leaving an OpenVMS Cluster by:
  - Providing interconnect redundancy between all systems.
  - Preventing resource exhaustion of disks and memory as well as saturation of interconnects, processors, and adapters.
– Using an uninterruptible power supply (UPS).
– Informing users that shutting off a workstation in a large OpenVMS Cluster disrupts the operation of all systems in the cluster.

• Do not use a quorum disk unless your OpenVMS Cluster has only two nodes.
• Where possible, ensure that shadow set members reside on shared buses to increase availability.
• The time to detect the failure of nodes, disks, adapters, interconnects, and virtual circuits is controlled by system polling parameters. Reducing polling time makes the cluster react quickly to changes, but it also results in lower tolerance to temporary outages. When setting timers, try to strike a balance between rapid recovery from significant failures and “nervousness” resulting from temporary failures.

Table 11–5 describes OpenVMS Cluster polling parameters that you can adjust for quicker detection time. Compaq recommends that these parameters be set to the same value in each OpenVMS Cluster.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QDSKINTERVAL</td>
<td>Specifies the quorum disk polling interval.</td>
</tr>
<tr>
<td>RECNXINTERVL</td>
<td>Specifies the interval during which the connection manager attempts to restore communication to another system.</td>
</tr>
<tr>
<td>T1MVCFAIL</td>
<td>Specifies the time required for detection of a virtual circuit failure.</td>
</tr>
</tbody>
</table>

• Include application recovery in your plans. When you assess the effect of a state transition on application users, consider that the application recovery phase includes activities such as replaying a journal file, cleaning up recovery units, and users logging in again.

Reference: For more detailed information about OpenVMS Cluster transitions and their phases, system parameters, quorum management, see OpenVMS Cluster Systems.

11.7 Migration and Warranted Support for Multiple Versions

Compaq provides two levels of support, warranted and migration, for mixed-version and mixed-architecture OpenVMS Cluster systems.

Warranted support means that Compaq has fully qualified the two versions coexisting in an OpenVMS Cluster and will answer all problems identified by customers using these configurations.

Migration support is a superset of the Rolling Upgrade support provided in earlier releases of OpenVMS and is available for mixes that are not warranted. Migration support means that Compaq has qualified the versions for use together in configurations that are migrating in a staged fashion to a newer version of OpenVMS VAX or of OpenVMS Alpha. Problem reports submitted against these configurations will be answered by Compaq. However, in exceptional cases, Compaq may request that you move to a warranted configuration as part of answering the problem.
Compaq supports only two versions of OpenVMS running in a cluster at the same time, regardless of architecture. Migration support helps customers move to warranted OpenVMS Cluster version mixes with minimal impact on their cluster environments.

Table 11–6 shows the level of support provided for all possible version pairings.

<table>
<thead>
<tr>
<th>OpenVMS Cluster Warranted and Migration Support</th>
<th>Alpha/VAX V7.3</th>
<th>Alpha V7.2–xxx/ VAX V7.2</th>
<th>Alpha/VAX V7.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alpha/VAX V7.3</td>
<td>WARRANTED</td>
<td>Migration</td>
<td>Migration</td>
</tr>
<tr>
<td>Alpha V7.2–xxx/ VAX V7.2</td>
<td>Migration</td>
<td>WARRANTED</td>
<td>Migration</td>
</tr>
<tr>
<td>Alpha/VAX V7.1</td>
<td>Migration</td>
<td>Migration</td>
<td>WARRANTED</td>
</tr>
</tbody>
</table>

In a mixed-version cluster, you must install remedial kits on earlier versions of OpenVMS. For OpenVMS Version 7.3, two new features, XFC and Volume Shadowing minicopy, cannot be run on any node in a mixed version cluster unless all nodes running earlier versions of OpenVMS have installed the required remedial kits. Remedial kits are available for both features for all versions, except for Volume Shadowing minicopy for OpenVMS Alpha/VAX Version 7.1.

For a complete list of required remedial kits, see the OpenVMS Version 7.3 Release Notes.

11.8 Alpha and VAX Systems in the Same OpenVMS Cluster

OpenVMS Alpha and OpenVMS VAX systems can work together in the same OpenVMS Cluster to provide both flexibility and migration capability. You can add Alpha processing power to an existing VAX cluster, enabling you to utilize applications that are system specific or hardware specific.

Table 11–6 depicts the OpenVMS version pairs for which Compaq provides migration and warranted support.

11.8.1 OpenVMS Cluster Satellite Booting Across Architectures

OpenVMS Alpha Version 7.1 and OpenVMS VAX Version 7.1 enable VAX boot nodes to provide boot service to Alpha satellites and Alpha boot nodes to provide boot service to VAX satellites. This support, called cross-architecture booting, increases configuration flexibility and higher availability of boot servers for satellites.

Two configuration scenarios make cross-architecture booting desirable:

- You want the Alpha system disk configured in the same highly available and high-performance area as your VAX system disk.

- Your Alpha boot server shares CI or DSSI storage with the VAX boot server. If your only Alpha boot server fails, you want to be able to reboot an Alpha satellite before the Alpha boot server reboots.
11.8.2 Restrictions

You cannot perform OpenVMS operating system and layered product installations and upgrades across architectures. For example, you must install and upgrade OpenVMS Alpha software using an Alpha system. When you configure OpenVMS Cluster systems that take advantage of cross-architecture booting, ensure that at least one system from each architecture is configured with a disk that can be used for installations and upgrades.

System disks can contain only a single version of the OpenVMS operating system and are architecture specific. For example, OpenVMS VAX Version 7.1 cannot coexist on a system disk with OpenVMS Alpha Version 7.1.

11.9 Determining Backup and Storage Management Strategies

In any system, hardware and electrical failures as well as human errors occur. All important data must be backed up to limit the effects of these errors. You can do this in a number of ways, depending on the time and resources available.

11.9.1 Steps for Determining a Backup Strategy

Follow these steps to determine a backup strategy:

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Decide how much lost work is acceptable in the event of a failure. This determines how often the data needs to be backed up.</td>
</tr>
<tr>
<td>2</td>
<td>Decide how long the data can remain unavailable while it is being backed up. This determines the methods of backup.</td>
</tr>
<tr>
<td>3</td>
<td>Establish a backup schedule, including the frequency and times of the day and week that backups will occur. Determine:</td>
</tr>
<tr>
<td></td>
<td>- How much data will be backed up daily, weekly, and monthly?</td>
</tr>
<tr>
<td></td>
<td>- Will you conduct full or incremental backups? How often for each?</td>
</tr>
<tr>
<td>4</td>
<td>Make sure that sufficient backup media are available. Determine both the initial amount of backup media needed and its growth rate.</td>
</tr>
<tr>
<td>5</td>
<td>Determine if your backup strategy requires backup media to be stored off site.</td>
</tr>
</tbody>
</table>

11.10 Disk Backup

Table 11–7 describes ways to provide a copy of data for backup.
OpenVMS Cluster System Management Strategies

11.10 Disk Backup

<table>
<thead>
<tr>
<th>Type of Data</th>
<th>Backup Method</th>
</tr>
</thead>
</table>
| Database is continually changing; transactions cannot be lost. | Use a combination of database backup (at a time when it is known to be static) and journaling transactions to the database. **Reference:** See the following manuals for additional information:  
  • RMS Journaling for OpenVMS Manual  
  • Guide to OpenVMS File Applications  
  • DEC Rdb Guide to Database Design and Definition  
  • DEC DBMS Database Design Guide  
  • DEC DBMS Database Maintenance and Performance Guide |

| Data must be accessible at all times, including nights and weekends. | Use Volume Shadowing for OpenVMS software to accomplish rapid disk backup. Remove a member from a three-member shadow set by dismounting the shadow set, remounting the shadow set with two members, and copying the third disk to magnetic tape. After this, the third disk can be included again in the shadow set. |

| Data can be unavailable for an extended period of time for backup. | Use the OpenVMS Backup utility (BACKUP) to make an image backup of a volume or a file-by-file copy of specified sets of files. BACKUP can make a copy to another disk (or set of disks) or to magnetic tape. Restoring from an image copy requires that the entire image be written to a disk. When you restore specific files, they are copied from the restored disk to the intended destination. On the other hand, an image copy is faster than a file-by-file copy, which copies files one at a time. Restoring a single file from the backup copy is easy. Also, a file-by-file restore greatly reduces fragmentation of the restored disk. |

| Data is static. | Archiving copies of the data on magnetic tape and excluding the online files from other backup procedures may be sufficient. Examples are program sources, documentation files, and distribution kits. |

| Scratch files and intermediate files. | You can choose not to provide any backup for these files. |

11.11 Tape Backup

Backup tape storage provides the least expensive storage medium. Tapes are the most common medium for offline storage and provide a range of capacities, cost, and shelf life. In general, tape storage is removable and generally off line.

11.11.1 For More Information

Backup procedures are described in detail in the following manuals:

• OpenVMS System Manager’s Manual

• OpenVMS System Management Utilities Reference Manual

11.11.2 Benefits of Unattended Backup

With current tape-drive technology, you can initiate a large backup operation that completes without operator intervention (that is, changing tapes). Such unattended backups can save significant time and reduce staffing costs. Cartridge tape loaders with tape magazines, such as the Tx8x7 or the TA91, allow unattended backups of up to nearly 42 GB of online storage. Backups can also be performed on robot-accessible media, such as the StorageTek 4400 ACS through the TC44 interconnect adapter, which provides terabyte capacity for backup archives.
11.11.3 Archive/Backup System for OpenVMS

Archive/Backup System for OpenVMS is a replacement for the Storage Library System (SLS). Archive/Backup provides lower system management costs, reduced equipment costs, and data security. It uses the POLYCENTER Media Library Manager (MLM) and the POLYCENTER Media Robot Manager (MRM) to move data to inexpensive tapes, and allows you to find and restore backed up and archived data easily. POLYCENTER MLM and MRM are the first Compaq products to provide OpenVMS users secure, highly reliable, fully automated access to tape and optical removable media through cost-effective media robots, such as the Odetics 5480 and the Tx8x7 family.

11.11.4 StorageTek 4400 ACS

You can attach the StorageTek 4400 ACS, a storage silo, to either an HSC using the TC44 adapter or directly to the XMI bus of a system using a KCM44 adapter. The StorageTek Silo automates access to a library of IBM 3480 compatible cartridge tapes. The library can contain up to 16 library storage modules. Each module can hold up to 1.2 TB of data in 6000 tape cartridges. A robotic arm can find and mount a requested tape within 45 to 90 seconds. Data movement for tape applications, such as the OpenVMS Backup utility, is performed the same way as with a TA90 tape drive.

11.11.5 Tape-Drive Performance and Capacity

Table 11–8 describes the performance and capacity of various tape drives and the interconnects to which they attach.

<table>
<thead>
<tr>
<th>Interconnect</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI (STI tapes)</td>
<td>The TA92 can transfer at a rate of 2.6 MB/s. Its magazine of IBM 3480 compatible cartridge tapes lets it back up 38 GB unattended. To achieve highest performance, connect the TA92 through a KDM70 controller or configure it with multiple CI adapters, so that the path to the tape drives is separate from the path to the disk drives.</td>
</tr>
<tr>
<td>DSSI</td>
<td>The TF867 offers the best tape performance. Its magazine of half-inch cartridge tapes can hold up to 42 GB of data for unattended backup. Its transfer rate is 0.8 MB/s. The TF857 can read TK50 and TK70 tapes, and its magazine can hold up to 18 GB of data.</td>
</tr>
<tr>
<td>SCSI</td>
<td>The TSZ07 allows SCSI configurations to access 9-track reel-to-reel tapes. It has a capacity of 140 MB per reel and a 750 KB/s transfer rate. The T2K10 offers a less expensive but slower-performing tape solution for SCSI configurations. It uses a quarter-inch cartridge that holds 525 MB and can transfer at a rate of 200 KB/s.</td>
</tr>
</tbody>
</table>
One of the benefits of OpenVMS Cluster systems is that multiple computers can simultaneously access storage devices connected to a OpenVMS Cluster storage interconnect. Together, these systems provide high performance and highly available access to storage.

This appendix describes how OpenVMS Cluster systems support the Small Computer Systems Interface (SCSI) as a storage interconnect. Multiple Alpha computers, also referred to as hosts or nodes, can simultaneously access SCSI disks over a SCSI interconnect. Such a configuration is called a SCSI multihost OpenVMS Cluster. A SCSI interconnect, also called a SCSI bus, is an industry-standard interconnect that supports one or more computers, peripheral devices, and interconnecting components.

The discussions in this chapter assume that you already understand the concept of sharing storage resources in an OpenVMS Cluster environment. OpenVMS Cluster concepts and configuration requirements are also described in the following OpenVMS Cluster documentation:

- OpenVMS Cluster Systems
- OpenVMS Cluster Software Software Product Description (SPD 29.78.xx)

This appendix includes two primary parts:

- Section A.1 through Section A.6.6 describe the fundamental procedures and concepts that you would need to plan and implement a SCSI multihost OpenVMS Cluster system.
- Section A.7 and its subsections provide additional technical detail and concepts.

## A.1 Conventions Used in This Appendix

Certain conventions are used throughout this appendix to identify the ANSI Standard and for elements in figures.

### A.1.1 SCSI ANSI Standard

OpenVMS Cluster systems configured with the SCSI interconnect must use standard SCSI–2 or SCSI–3 components. The SCSI–2 components must be compliant with the architecture defined in the American National Standards Institute (ANSI) Standard SCSI–2, X3T9.2, Rev. 10L. The SCSI–3 components must be compliant with approved versions of the SCSI–3 Architecture and Command standards. For ease of discussion, this appendix uses the term SCSI to refer to both SCSI–2 and SCSI–3.
SCSI as an OpenVMS Cluster Interconnect

A.2 Accessing SCSI Storage

In OpenVMS Cluster configurations, multiple VAX and Alpha hosts can directly access SCSI devices in any of the following ways:

- CI interconnect with HSJ or HSC controllers
- Digital Storage Systems Interconnect (DSSI) with HSD controller
- SCSI adapters directly connected to VAX or Alpha systems

You can also access SCSI devices indirectly using the OpenVMS MSCP server.

The following sections describe single-host and multihost access to SCSI storage devices.

A.2.1 Single-Host SCSI Access in OpenVMS Cluster Systems

Prior to OpenVMS Version 6.2, OpenVMS Cluster systems provided support for SCSI storage devices connected to a single host using an embedded SCSI adapter, an optional external SCSI adapter, or a special-purpose RAID (redundant arrays of independent disks) controller. Only one host could be connected to a SCSI bus.

A.2.2 Multihost SCSI Access in OpenVMS Cluster Systems

Beginning with OpenVMS Alpha Version 6.2, multiple Alpha hosts in an OpenVMS Cluster system can be connected to a single SCSI bus to share access to SCSI storage devices directly. This capability allows you to build highly available servers using shared access to SCSI storage.
Figure A–2 shows an OpenVMS Cluster configuration that uses a SCSI interconnect for shared access to SCSI devices. Note that another interconnect (for example, a local area network [LAN]) is required for host-to-host OpenVMS Cluster (System Communications Architecture [SCA]) communications.

You can build a three-node OpenVMS Cluster system using the shared SCSI bus as the storage interconnect, or you can include shared SCSI buses within a larger OpenVMS Cluster configuration. A quorum disk can be used on the SCSI bus to improve the availability of two- or three-node configurations. Host-based RAID (including host-based shadowing) and the MSCP server are supported for shared SCSI storage devices.

A.3 Configuration Requirements and Hardware Support

This section lists the configuration requirements and supported hardware for multihost SCSI OpenVMS Cluster systems.

A.3.1 Configuration Requirements

Table A–1 shows the requirements and capabilities of the basic software and hardware components you can configure in a SCSI OpenVMS Cluster system.
A.3 Configuration Requirements and Hardware Support

</tr>
<tr>
<td><strong>Hardware</strong></td>
<td>Table A–2 lists the supported hardware components for SCSI OpenVMS Cluster systems.</td>
</tr>
<tr>
<td></td>
<td>See also Section A.7.7 for information about other hardware devices that might be used in a SCSI OpenVMS Cluster configuration.</td>
</tr>
<tr>
<td><strong>SCSI tape, floppies, and CD-ROM drives</strong></td>
<td>You cannot configure SCSI tape drives, floppy drives, or CD-ROM drives on multihost SCSI interconnects. If your configuration requires SCSI tape, floppy, or CD-ROM drives, configure them on single-host SCSI interconnects. Note that SCSI tape, floppy, or CD-ROM drives may be MSCP or TMSCP served to other hosts in the OpenVMS Cluster configuration.</td>
</tr>
<tr>
<td><strong>Maximum hosts on a SCSI bus</strong></td>
<td>You can connect up to three hosts on a multihost SCSI bus. You can configure any mix of the hosts listed in Table A–2 on the same shared SCSI interconnect.</td>
</tr>
<tr>
<td><strong>Maximum SCSI buses per host</strong></td>
<td>You can connect each host to a maximum of six multihost SCSI buses. The number of nonshared (single-host) SCSI buses that can be configured is limited only by the number of available slots on the host bus.</td>
</tr>
<tr>
<td><strong>Host-to-host communication</strong></td>
<td>All members of the cluster must be connected by an interconnect that can be used for host-to-host (SCA) communication; for example, DSSI, CI, Ethernet, FDDI, or MEMORY CHANNEL.</td>
</tr>
<tr>
<td><strong>Host-based RAID (including host-based shadowing)</strong></td>
<td>Supported in SCSI OpenVMS Cluster configurations.</td>
</tr>
<tr>
<td><strong>SCSI device naming</strong></td>
<td>The name of each SCSI device must be unique throughout the OpenVMS Cluster system. When configuring devices on systems that include a multihost SCSI bus, adhere to the following requirements:</td>
</tr>
<tr>
<td></td>
<td>• A host can have, at most, one adapter attached to a particular SCSI interconnect.</td>
</tr>
<tr>
<td></td>
<td>• All host controllers attached to a given SCSI interconnect must have the same OpenVMS device name (for example, PKA0), unless port allocation classes are used (see OpenVMS Cluster Systems).</td>
</tr>
<tr>
<td></td>
<td>• Each system attached to a SCSI interconnect must have the a nonzero node disk allocation class value. These node disk allocation class values may differ as long as either of the following conditions is true:</td>
</tr>
<tr>
<td></td>
<td>− The SCSI interconnect has a positive, non-zero port allocation class</td>
</tr>
<tr>
<td></td>
<td>− The only devices attached to the SCSI interconnect are accessed by HSZ70 or HSZ80 controllers that have a non-zero controller allocation class.</td>
</tr>
<tr>
<td></td>
<td>If you have multiple SCSI interconnects, you must consider all the SCSI interconnects to determine whether you can choose a different value for the node disk allocation class on each system. Note, also, that the addition of a SCSI device to an existing SCSI interconnect requires a reevaluation of whether the node disk allocation classes can still be different. Therefore, Compaq recommends that you use the same node disk allocation class value for all systems attached to the same SCSI interconnect. For more information about allocation classes, see OpenVMS Cluster Systems.</td>
</tr>
</tbody>
</table>
A.3.2 Hardware Support

Table A–2 shows the supported hardware components for SCSI OpenVMS Cluster systems; it also lists the minimum required revision for these hardware components. That is, for any component, you must use either the version listed in Table A–2 or a subsequent version. For host support information, refer to the AlphaServer or AlphaStation documentation for your model on the following Compaq web site:

http://www.compaq.com/products/servers/

For disk support information, refer to StorageWorks product documentation on the Compaq web site:

http://www.compaq.com/storage/

The SCSI interconnect configuration and all devices on the SCSI interconnect must meet the requirements defined in the ANSI Standard SCSI–2 document, or the SCSI–3 Architecture and Command standards, and the requirements described in this appendix. See also Section A.7.7 for information about other hardware devices that might be used in a SCSI OpenVMS Cluster configuration.

¹Unless stated in this column, the minimum firmware version for a device is the same as required for the operating system version you are running. There are no additional firmware requirements for a SCSI multihost OpenVMS Cluster configuration.

²You can configure other types of SCSI adapters in a system for single-host access to local storage.

A.4 SCSI Interconnect Concepts

The SCSI standard defines a set of rules governing the interactions between initiators (typically, host systems) and SCSI targets (typically, peripheral devices). This standard allows the host to communicate with SCSI devices (such as disk drives, tape drives, printers, and optical media devices) without having to manage the device-specific characteristics.

The following sections describe the SCSI standard and the default modes of operation. The discussions also describe some optional mechanisms you can implement to enhance the default SCSI capabilities in areas such as capacity, performance, availability, and distance.
A.4 SCSI Interconnect Concepts

A.4.1 Number of Devices

The SCSI bus is an I/O interconnect that can support up to 16 devices. A narrow SCSI bus supports up to 8 devices; a wide SCSI bus support up to 16 devices. The devices can include host adapters, peripheral controllers, and discrete peripheral devices such as disk or tape drives. The devices are addressed by a unique ID number from 0 through 15. You assign the device IDs by entering console commands, or by setting jumpers or switches, or by selecting a slot on a StorageWorks enclosure.

Note

In order to connect 16 devices to a wide SCSI bus, the devices themselves must also support wide addressing. Narrow devices do not talk to hosts above ID 7. Presently, the HSZ40 does not support addresses above 7. Host adapters that support wide addressing are KZTSA, KZPSA, and the QLogic wide adapters (KZPBA, KZPDA, ITIOP, P1SE, and P2SE). Only the KZPBA-CB is supported in a multihost SCSI OpenVMS Cluster configuration.

When configuring more devices than the previous limit of eight, make sure that you observe the bus length requirements (see Table A–4).

To configure wide IDs on a BA356 box, refer to the BA356 manual StorageWorks Solutions BA356-SB 16-Bit Shelf User’s Guide (order number EK-BA356-UG). Do not configure a narrow device in a BA356 box that has a starting address of 8.

To increase the number of devices on the SCSI interconnect, some devices implement a second level of device addressing using logical unit numbers (LUNs). For each device ID, up to eight LUNs (0–7) can be used to address a single SCSI device as multiple units. The maximum number of LUNs per device ID is eight.

Note

When connecting devices to a SCSI interconnect, each device on the interconnect must have a unique device ID. You may need to change a device’s default device ID to make it unique. For information about setting a single device’s ID, refer to the owner’s guide for the device.

A.4.2 Performance

The default mode of operation for all SCSI devices is 8-bit asynchronous mode. This mode, sometimes referred to as narrow mode, transfers 8 bits of data from one device to another. Each data transfer is acknowledged by the device receiving the data. Because the performance of the default mode is limited, the SCSI standard defines optional mechanisms to enhance performance. The following list describes two optional methods for achieving higher performance:

- Increase the amount of data that is transferred in parallel on the interconnect. The 16-bit and 32-bit wide options allow a doubling or quadrupling of the data rate, respectively. Because the 32-bit option is seldom implemented, this appendix discusses only 16-bit operation and refers to it as wide.
• Use synchronous data transfer. In synchronous mode, multiple data transfers can occur in succession, followed by an acknowledgment from the device receiving the data. The standard defines a slow mode (also called standard mode) and a fast mode for synchronous data transfers:
  – In standard mode, the interconnect achieves up to 5 million transfers per second.
  – In fast mode, the interconnect achieves up to 10 million transfers per second.
  – In ultra mode, the interconnect achieves up to 20 million transfers per second.

Because all communications on a SCSI interconnect occur between two devices at a time, each pair of devices must negotiate to determine which of the optional features they will use. Most, if not all, SCSI devices implement one or more of these options.

Table A–3 shows data rates when using 8- and 16-bit transfers with standard, fast, and ultra synchronous modes.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Narrow (8-bit)</th>
<th>Wide (16-bit)</th>
</tr>
</thead>
<tbody>
<tr>

<td>5</td>
<td>10</td>
</tr>
<tr>
<td>Fast</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>Ultra</td>
<td>20</td>
<td>40</td>
</tr>
</tbody>
</table>

A.4.3 Distance

The maximum length of the SCSI interconnect is determined by the signaling method used in the configuration and by the data transfer rate. There are two types of electrical signaling for SCSI interconnects:

• Single-ended signaling
  The single-ended method is the most common and the least expensive. The distance spanned is generally modest.

• Differential signaling
  This method provides higher signal integrity, thereby allowing a SCSI bus to span longer distances.

Table A–4 summarizes how the type of signaling method affects SCSI interconnect distances.

<table>
<thead>
<tr>
<th>Signaling Technique</th>
<th>Rate of Data Transfer</th>
<th>Maximum Cable Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single ended</td>
<td>Standard</td>
<td>6 m(^1)</td>
</tr>
<tr>
<td>Single ended</td>
<td>Fast</td>
<td>3 m</td>
</tr>
</tbody>
</table>

\(^1\)The SCSI standard specifies a maximum length of 6 m for this type of interconnect. However, where possible, it is advisable to limit the cable length to 4 m to ensure the highest level of data integrity.

(continued on next page)

</tr>
<tr>
<td>Differential</td>
<td>Ultra</td>
<td>25.5 m²</td>
</tr>
</tbody>
</table>

For more information, refer to the StorageWorks UltraSCSI Configuration Guidelines, order number EK-ULTRA-CG.

The DWZZA, DWZZB, and DWZZC converters are single-ended to differential converters that you can use to connect single-ended and differential SCSI interconnect segments. The DWZZA is for narrow (8-bit) SCSI buses, the DWZZB is for wide (16-bit) SCSI buses, and the DWZZC is for wide Ultra SCSI buses.

The differential segments are useful for the following:

- Overcoming the distance limitations of the single-ended interconnect
- Allowing communication between single-ended and differential devices

Because the DWZZA, the DWZZB, and the DWZZC are strictly signal converters, you cannot assign a SCSI device ID to them. You can configure a maximum of two DWZZA or two DWZZB converters in the path between any two SCSI devices. Refer to the StorageWorks UltraSCSI Configuration Guidelines for information on configuring the DWZZC.

A.4.4 Cabling and Termination

Each single-ended and differential SCSI interconnect must have two terminators, one at each end. The specified maximum interconnect lengths are measured from terminator to terminator.

The interconnect terminators are powered from the SCSI interconnect line called TERMPWR. Each StorageWorks host adapter and enclosure supplies the TERMPWR interconnect line, so that as long as one host or enclosure is powered on, the interconnect remains terminated.

Devices attach to the interconnect by short cables (or etch) called stubs. Stubs must be short in order to maintain the signal integrity of the interconnect. The maximum stub lengths allowed are determined by the type of signaling used by the interconnect, as follows:

- For single-ended interconnects, the maximum stub length is .1 m.
- For differential interconnects, the maximum stub length is .2 m.

Additionally, the minimum distance between stubs on a single-ended interconnect is .3 m. Refer to Figure A–3 for an example of this configuration.

Note

Terminate single-ended and differential buses individually, even when using DWZZx converters.
When you are extending the SCSI bus beyond an existing terminator, it is necessary to disable or remove that terminator.

Figure A–3 Maximum Stub Lengths

A.5 SCSI OpenVMS Cluster Hardware Configurations

The hardware configuration that you choose depends on a combination of factors:

- Your computing needs—for example, continuous availability or the ability to disconnect or remove a system from your SCSI OpenVMS Cluster system
- Your environment—for example, the physical attributes of your computing facility
- Your resources—for example, your capital equipment or the available PCI slots

Refer to the OpenVMS Cluster Software Software Product Description (SPD 29.78.xx) for configuration limits.

The following sections provide guidelines for building SCSI configurations and describe potential configurations that might be suitable for various sites.

A.5.1 Systems Using Add-On SCSI Adapters

Shared SCSI bus configurations typically use optional add-on KZPAA, KZPSA, KZPBA, and KZTSA adapters. These adapters are generally easier to configure than internal adapters because they do not consume any SCSI cable length. Additionally, when you configure systems using add-on adapters for the shared SCSI bus, the internal adapter is available for connecting devices that cannot be shared (for example, SCSI tape, floppy, and CD-ROM drives).

When using add-on adapters, storage is configured using BA350, BA353, or HSZxx StorageWorks enclosures. These enclosures are suitable for all data disks, and for shared OpenVMS Cluster system and quorum disks. By using StorageWorks enclosures, it is possible to shut down individual systems without losing access to the disks.

The following sections describe some SCSI OpenVMS Cluster configurations that take advantage of add-on adapters.
A.5.1.1 Building a Basic System Using Add-On SCSI Adapters

Figure A–4 shows a logical representation of a basic configuration using SCSI adapters and a StorageWorks enclosure. This configuration has the advantage of being relatively simple, while still allowing the use of tapes, floppies, CD-ROMs, and disks with nonshared files (for example, page files and swap files) on internal buses. Figure A–5 shows this type of configuration using AlphaServer 1000 systems and a BA350 enclosure.

The BA350 enclosure uses 0.9 m of SCSI cabling, and this configuration typically uses two 1-m SCSI cables. (A BA353 enclosure also uses 0.9 m, with the same total cable length.) The resulting total cable length of 2.9 m allows fast SCSI mode operation.

Although the shared BA350 storage enclosure is theoretically a single point of failure, this basic system is a very reliable SCSI OpenVMS Cluster configuration. When the quorum disk is located in the BA350, you can shut down either of the AlphaStation systems independently while retaining access to the OpenVMS Cluster system. However, you cannot physically remove the AlphaStation system, because that would leave an unterminated SCSI bus.

If you need the ability to remove a system while your OpenVMS Cluster system remains operational, build your system using DWZx converters, as described in Section A.5.1.2. If you need continuous access to data if a SCSI interconnect fails, you should do both of the following:

- Add a redundant SCSI interconnect with another BA350 shelf.
- Shadow the data.

In Figure A–4 and the other logical configuration diagrams in this appendix, the required network interconnect is not shown.

Figure A–4 Conceptual View: Basic SCSI System
A.5.1.2 Building a System with More Enclosures or Greater Separation or with HSZ Controllers

If you need additional enclosures, or if the needs of your site require a greater physical separation between systems, or if you plan to use HSZ controllers, you can use a configuration in which DWZZx converters are placed between systems with single-ended signaling and a differential-cabled SCSI bus.

DWZZx converters provide additional SCSI bus length capabilities, because the DWZZx allows you to connect a single-ended device to a bus that uses differential signaling. As described in Section A.4.3, SCSI bus configurations that use differential signaling may span distances up to 25 m, whereas single-ended configurations can span only 3 m when fast-mode data transfer is used.

DWZZx converters are available as standalone, desktop components or as StorageWorks compatible building blocks. DWZZx converters can be used with the internal SCSI adapter or the optional KZPAA adapters.

The HSZ40 is a high-performance differential SCSI controller that can be connected to a differential SCSI bus, and supports up to 72 SCSI devices. An HSZ40 can be configured on a shared SCSI bus that includes DWZZx single-ended to differential converters. Disk devices configured on HSZ40 controllers can be combined into RAID sets to further enhance performance and provide high availability.
Figure A-6 shows a logical view of a configuration that uses additional DWZZAs to increase the potential physical separation (or to allow for additional enclosures and HSZ40s), and Figure A-7 shows a sample representation of this configuration.

Figure A-6   Conceptual View: Using DWZZAs to Allow for Increased Separation or More Enclosures
Figure A–7 Sample Configuration: Using DWZZAs to Allow for Increased Separation or More Enclosures
Figure A–8 shows how a three-host SCSI OpenVMS Cluster system might be configured.

Figure A–8 Sample Configuration: Three Hosts on a SCSI Bus
A.5.1.3 Building a System That Uses Differential Host Adapters

Figure A–9 is a sample configuration with two KZPSA adapters on the same SCSI bus. In this configuration, the SCSI termination has been removed from the KZPSA, and external terminators have been installed on “Y” cables. This allows you to remove the KZPSA adapter from the SCSI bus without rendering the SCSI bus inoperative. The capability of removing an individual system from your SCSI OpenVMS Cluster configuration (for maintenance or repair) while the other systems in the cluster remain active gives you an especially high level of availability.

Please note the following about Figure A–9:

- Termination is removed from the host adapter.
- Termination for the single-ended bus inside the BA356 is provided by the DWZZB in slot 0 and by the automatic terminator on the personality module. (No external cables or terminators are attached to the personality module.)
- The DWZZB’s differential termination is removed.
The differential SCSI bus in the configuration shown in Figure A–9 is chained from enclosure to enclosure and is limited to 25 m in length. (The BA356 does not add to the differential SCSI bus length. The differential bus consists only of the BN21W-0B “Y” cables and the BN21K/BN21L cables.) In configurations where this cabling scheme is inconvenient or where it does not provide adequate distance, an alternative radial scheme can be used.

The radial SCSI cabling alternative is based on a SCSI hub. Figure A–10 shows a logical view of the SCSI hub configuration, and Figure A–11 shows a sample representation of this configuration.
Figure A–10 Conceptual View: SCSI System Using a SCSI Hub
Figure A–11 shows a sample representation of a SCSI hub configuration.

**Figure A–11 Sample Configuration: SCSI System with SCSI Hub Configuration**

![Diagram of a sample SCSI system with a hub configuration]

**A.6 Installation**

This section describes the steps required to set up and install the hardware in a SCSI OpenVMS Cluster system. The assumption in this section is that a new OpenVMS Cluster system, based on a shared SCSI bus, is being created. If, on the other hand, you are adding a shared SCSI bus to an existing OpenVMS Cluster configuration, then you should integrate the procedures in this section with those described in OpenVMS Cluster Systems to formulate your overall installation plan.

Table A–5 lists the steps required to set up and install the hardware in a SCSI OpenVMS Cluster system.
**Table A–5  Steps for Installing a SCSI OpenVMS Cluster System**

**A.6.1 Step 1: Meet SCSI Grounding Requirements**

You must ensure that your electrical power distribution systems meet local requirements (for example, electrical codes) prior to installing your OpenVMS Cluster system. If your configuration consists of two or more enclosures connected by a common SCSI interconnect, you must also ensure that the enclosures are properly grounded. Proper grounding is important for safety reasons and to ensure the proper functioning of the SCSI interconnect.

Electrical work should be done by a qualified professional. Section A.7.8 includes details of the grounding requirements for SCSI systems.

**A.6.2 Step 2: Configure SCSI Node IDs**

This section describes how to configure SCSI node and device IDs. SCSI IDs must be assigned separately for multihost SCSI buses and single-host SCSI buses.

Figure A–12 shows two hosts; each one is configured with a single-host SCSI bus and shares a multihost SCSI bus. (See Figure A–1 for the key to the symbols used in this figure.)
The following sections describe how IDs are assigned in this type of multihost SCSI configuration. For more information about this topic, see OpenVMS Cluster Systems.

### A.6.2.1 Configuring Device IDs on Multihost SCSI Buses

When configuring multihost SCSI buses, adhere to the following rules:

- Set each host adapter on the multihost bus to a different ID. Start by assigning ID 7, then ID 6, and so on, using decreasing ID numbers.
  
  If a host has two multihost SCSI buses, allocate an ID to each SCSI adapter separately. There is no requirement that you set the adapters to the same ID, although using the same ID may simplify configuration management. (Section A.6.4 describes how to set host IDs for the internal adapter using SCSI console parameters.)

- When assigning IDs to devices and storage controllers connected to multihost SCSI buses, start at ID 0 (zero), assigning the highest ID numbers to the disks that require the fastest I/O response time.

- Devices connected to a multihost SCSI bus must have the same name as viewed from each host. To achieve this, you must do one of the following:
  - Ensure that all hosts connected to a multihost SCSI bus are set to the same node allocation class, and all host adapters connected to a multihost SCSI bus have the same controller letter, as shown in Figure A–12.
  - Use port allocation classes (see OpenVMS Cluster Systems) or HSZ allocation classes (see Guidelines for OpenVMS Cluster Configurations).
A.6.2.2 Configuring Device IDs on Single-Host SCSI Buses

The device ID selection depends on whether you are using a node allocation class or a port allocation class. The following discussion applies to node allocation classes. Refer to OpenVMS Cluster Systems for a discussion of port allocation classes.

In multihost SCSI configurations, device names generated by OpenVMS use the format $allocation_class$DKA300. You set the allocation class using the ALLCLASS system parameter. OpenVMS generates the controller letter (for example, A, B, C, and so forth) at boot time by allocating a letter to each controller. The unit number (for example, 0, 100, 200, 300, and so forth) is derived from the SCSI device ID.

When configuring devices on single-host SCSI buses that are part of a multihost SCSI configuration, take care to ensure that the disks connected to the single-host SCSI buses have unique device names. Do this by assigning different IDs to devices connected to single-host SCSI buses with the same controller letter on systems that use the same allocation class. Note that the device names must be different, even though the bus is not shared.

For example, in Figure A–12, the two disks at the bottom of the picture are located on SCSI bus A of two systems that use the same allocation class. Therefore, they have been allocated different device IDs (in this case, 2 and 3).

For a given allocation class, SCSI device type, and controller letter (in this example, $4$DKA), there can be up to eight devices in the cluster, one for each SCSI bus ID. To use all eight IDs, it is necessary to configure a disk on one SCSI bus at the same ID as a processor on another bus. See Section A.7.5 for a discussion of the possible performance impact this can have.

SCSI bus IDs can be effectively “doubled up” by configuring different SCSI device types at the same SCSI ID on different SCSI buses. For example, device types DK and MK could produce $4$DKA100 and $4$MKA100.

A.6.3 Step 3: Power Up and Verify SCSI Devices

After connecting the SCSI cables, power up the system. Enter a console SHOW DEVICE command to verify that all devices are visible on the SCSI interconnect.

If there is a SCSI ID conflict, the display may omit devices that are present, or it may include nonexistent devices. If the display is incorrect, then check the SCSI ID jumpers on devices, the automatic ID assignments provided by the StorageWorks shelves, and the console settings for host adapter and HSZxx controller IDs. If changes are made, type INIT, then SHOW DEVICE again. If problems persist, check the SCSI cable lengths and termination.
Example A–1 is a sample output from a console SHOW DEVICE command. This system has one host SCSI adapter on a private SCSI bus (PKA0), and two additional SCSI adapters (PKB0 and PKC0), each on separate, shared SCSI buses.

Example A–1  SHOW DEVICE Command Sample Output

```
>>>SHOW DEVICE
dka0.0.0.6.0    DKA0          RZ26L  442D
dka400.4.0.6.0   DKA400        RRD43  2893
dkb100.1.0.11.0  DKB100        RZ26  392A
dkb200.2.0.11.0  DKB200        RZ26L  442D
dkc400.4.0.12.0  DKC400        HSZ40  V25
dkc401.4.0.12.0  DKC401        HSZ40  V25
dkc500.5.0.12.0  DKC500        HSZ40  V25
dkc501.5.0.12.0  DKC501        HSZ40  V25
dkc506.5.0.12.0  DKC506        HSZ40  V25
dva0.0.0.0.1     DVA0
jkb700.7.0.11.0  JKB700        OpenVMS V62
jkc700.7.0.12.0  JKC700        OpenVMS V62
mka300.3.0.6.0   MKA300        TLZ06  0389
era0.0.0.2.1    ERA0          08-00-2B-3F-3A-B9
pkao.7.0.6.0    PKAO          SCSI Bus ID 7
pkbo.6.0.11.0   PKBO          SCSI Bus ID 6
pkco.6.0.12.0   PKCO          SCSI Bus ID 6
```

The following list describes the device names in the preceding example:

- **DK devices** represent SCSI disks. Disks connected to the SCSI bus controlled by adapter PKA are given device names starting with the letters DKA. Disks on additional buses are named according to the host adapter name in a similar manner (DKB devices on adapter PKB, and so forth). The next character in the device name represents the device’s SCSI ID. Make sure that the SCSI ID for each device is unique for the SCSI bus to which it is connected.

- The last digit in the DK device name represents the LUN number. The HSZ40 virtual DK device in this example is at SCSI ID 4, LUN 1. Note that some systems do not display devices that have nonzero LUNs.

- **JK devices** represent nondisk or nontape devices on the SCSI interconnect. In this example, JK devices represent other processors on the SCSI interconnect that are running the OpenVMS operating system. If the other system is not running, these JK devices do not appear in the display. In this example, the other processor’s adapters are at SCSI ID 7.

- **MK devices** represent SCSI tapes. The A in device MKA300 indicates that it is attached to adapter PKA0, the private SCSI bus.

- **PK devices** represent the local SCSI adapters. The SCSI IDs for these adapters is displayed in the rightmost column. Make sure this is different from the IDs used by other devices and host adapters on its bus. The third character in the device name (in this example, a) is assigned by the system so that each adapter has a unique name on that system. The fourth character is always zero.
A.6.4 Step 4: Show and Set SCSI Console Parameters

When creating a SCSI OpenVMS Cluster system, you need to verify the settings of the console environment parameters shown in Table A–6 and, if necessary, reset their values according to your configuration requirements.

Table A–6 provides a brief description of SCSI console parameters. Refer to your system-specific documentation for complete information about setting these and other system parameters.

Note

The console environment parameters vary, depending on the host adapter type. Refer to the Installation and User’s Guide for your adapter.

Table A–6  SCSI Environment Parameters

<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
<tr>
<td>control_scsi_term</td>
<td>Enables and disables the terminator on the integral SCSI interconnect at the</td>
</tr>
<tr>
<td></td>
<td>system bulkhead (for some systems).</td>
</tr>
</tbody>
</table>

Note

If you need to modify any parameters, first change the parameter (using the appropriate console SET command). Then enter a console INIT command or press the Reset button to make the change effective.

Examples

Before setting boot parameters, display the current settings of these parameters, as shown in the following examples:

1.

```plaintext
>>>SHOW *BOOT*
boot_osflags       10,0
boot_reset         OFF
bootdef_dev        dka200.2.0.6.0
>>>```

SCSI as an OpenVMS Cluster Interconnect  A–23
A.6 Installation

The first number in the boot_osflags parameter specifies the system root. (In this example, the first number is 10.) The boot_reset parameter controls the boot process. The default boot device is the device from which the OpenVMS operating system is loaded. Refer to the documentation for your specific system for additional booting information.

Note that you can identify multiple boot devices to the system. By doing so, you cause the system to search for a bootable device from the list of devices that you specify. The system then automatically boots from the first device on which it finds bootable system software. In addition, you can override the default boot device by specifying an alternative device name on the boot command line.

Typically, the default boot flags suit your environment. You can override the default boot flags by specifying boot flags dynamically on the boot command line with the -flags option.

2. >>>SHOW *PK*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>pka0_disconnect</td>
<td>1</td>
</tr>
<tr>
<td>pka0_fast</td>
<td>1</td>
</tr>
<tr>
<td>pka0_host_id</td>
<td>7</td>
</tr>
</tbody>
</table>

The pk*0_disconnect parameter determines whether or not a target is allowed to disconnect from the SCSI bus while it acts on a command. On a multihost SCSI bus, the pk*0_disconnect parameter must be set to 1, so that disconnects can occur.

The pk*0_fast parameter controls whether fast SCSI devices on a SCSI controller perform in standard or fast mode. When the parameter is set to 0, the default speed is set to standard mode; when the pk*0_fast parameter is set to 1, the default speed is set to fast SCSI mode. In this example, devices on SCSI controller pka0 are set to fast SCSI mode. This means that both standard and fast SCSI devices connected to this controller will automatically perform at the appropriate speed for the device (that is, in either fast or standard mode).

The pk*0_host_id parameter assigns a bus node ID for the specified host adapter. In this example, pka0 is assigned a SCSI device ID of 7.

3. >>>SHOW *POLL*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>scsi_poll</td>
<td>ON</td>
</tr>
</tbody>
</table>

Enables or disables polling of SCSI devices while in console mode.

Set polling ON or OFF depending on the needs and environment of your site. When polling is enabled, the output of the SHOW DEVICE is always up to date. However, because polling can consume SCSI bus bandwidth (proportional to the number of unused SCSI IDs), you might want to disable polling if one system on a multihost SCSI bus will be in console mode for an extended time.

Polling must be disabled during any hot-plugging operations. For information about hot plugging in a SCSI OpenVMS Cluster environment, see Section A.7.6.
4.

>>>SHOW *TERM*
control_scsi_term      external

Used on some systems (such as the AlphaStation 400) to enable or disable the SCSI terminator next to the external connector. Set the control_scsi_term parameter to external if a cable is attached to the bulkhead. Otherwise, set the parameter to internal.

A.6.5 Step 5: Install the OpenVMS Operating System

Refer to the OpenVMS Alpha or VAX upgrade and installation manual for information about installing the OpenVMS operating system. Perform the installation once for each system disk in the OpenVMS Cluster system. In most configurations, there is a single system disk. Therefore, you need to perform this step once, using any system.

During the installation, when you are asked if the system is to be a cluster member, answer Yes. Then, complete the installation according to the guidelines provided in OpenVMS Cluster Systems.

A.6.6 Step 6: Configure Additional Systems

Use the CLUSTER_CONFIG command procedure to configure additional systems. Execute this procedure once for the second host that you have configured on the SCSI bus. (See Section A.7.1 for more information.)

A.7 Supplementary Information

The following sections provide supplementary technical detail and concepts about SCSI OpenVMS Cluster systems.

A.7.1 Running the OpenVMS Cluster Configuration Command Procedure

You execute either the CLUSTER_CONFIG.COM or the CLUSTER_CONFIG_LAN.COM command procedure to set up and configure nodes in your OpenVMS Cluster system. Your choice of command procedure depends on whether you use DECnet or the LANCP utility for booting. CLUSTER_CONFIG.COM uses DECnet; CLUSTER_CONFIG_LAN.COM uses the LANCP utility. (For information about using both procedures, see OpenVMS Cluster Systems.)

Typically, the first computer is set up as an OpenVMS Cluster system during the initial OpenVMS installation procedure (see Section A.6.5). The CLUSTER_CONFIG procedure is then used to configure additional nodes. However, if you originally installed OpenVMS without enabling clustering, the first time you run CLUSTER_CONFIG, the procedure converts the standalone system to a cluster system.

To configure additional nodes in a SCSI cluster, execute CLUSTER_CONFIG.COM for each additional node. Table A–7 describes the steps to configure additional SCSI nodes.
**Table A–7  Steps for Installing Additional Nodes**

<table>
<thead>
<tr>
<th>Step</th>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>From the first node, run the CLUSTER_CONFIG.COM procedure and select the default option [1] for ADD.</td>
</tr>
<tr>
<td>2</td>
<td>Answer Yes when CLUSTER_CONFIG.COM asks whether you want to proceed.</td>
</tr>
<tr>
<td>3</td>
<td>Supply the DECnet name and address of the node that you are adding to the existing single-node cluster.</td>
</tr>
<tr>
<td>4</td>
<td>Confirm that this will be a node with a shared SCSI interconnect.</td>
</tr>
<tr>
<td>5</td>
<td>Answer No when the procedure asks whether this node will be a satellite.</td>
</tr>
<tr>
<td>6</td>
<td>Configure the node to be a disk server if it will serve disks to other cluster members.</td>
</tr>
<tr>
<td>7</td>
<td>Place the new node’s system root on the default device offered.</td>
</tr>
<tr>
<td>8</td>
<td>Select a system root for the new node. The first node uses SYS0. Take the default (SYS10 for the first additional node), or choose your own root numbering scheme. You can choose from SYS1 to SYSn, where n is hexadecimal FFFF.</td>
</tr>
<tr>
<td>9</td>
<td>Select the default disk allocation class so that the new node in the cluster uses the same ALLOCCLASS as the first node.</td>
</tr>
<tr>
<td>10</td>
<td>Confirm whether or not there is a quorum disk.</td>
</tr>
<tr>
<td>11</td>
<td>Answer the questions about the sizes of the page file and swap file.</td>
</tr>
</tbody>
</table>
| 12   | When CLUSTER_CONFIG.COM completes, boot the new node from the new system root. For example, for SYSFF on disk DKA200, enter the following command:  

```
BOOT -FL FF,0 DKA200
```

In the BOOT command, you can use the following flags:

- -FL indicates boot flags.
- FF is the new system root.
- 0 means there are no special boot requirements, such as conversational boot.

You can run the CLUSTER_CONFIG.COM procedure to set up an additional node in a SCSI cluster, as shown in Example A–2.

**Example A–2  Adding a Node to a SCSI Cluster**

```
$ @SYS$MANAGER:CLUSTER_CONFIG
```

**Cluster Configuration Procedure**

Use CLUSTER_CONFIG.COM to set up or change an OpenVMS Cluster configuration. To ensure that you have the required privileges, invoke this procedure from the system manager’s account.

Enter ? for help at any prompt:

1. ADD a node to a cluster.
2. REMOVE a node from the cluster.
3. CHANGE a cluster member’s characteristics.
4. CREATE a duplicate system disk for CLU21.
5. EXIT from this procedure.

Enter choice [1]:

The ADD function adds a new node to a cluster.

(continued on next page)
Example A–2 (Cont.) Adding a Node to a SCSI Cluster

If the node being added is a voting member, EXPECTED_VOTES in every cluster member’s MODPARAMS.DAT must be adjusted, and the cluster must be rebooted.

WARNING - If this cluster is running with multiple system disks and if common system files will be used, please, do not proceed unless you have defined appropriate logical names for cluster common files in SYLOGICALS.COM. For instructions, refer to the OpenVMS Cluster Systems manual.

Do you want to continue [N]? y

If the new node is a satellite, the network databases on CLU21 are updated. The network databases on all other cluster members must be updated.

For instructions, refer to the OpenVMS Cluster Systems manual.

What is the node’s DECnet node name? SATURN
What is the node’s DECnet node address? 7.77
Is SATURN to be a clustered node with a shared SCSI bus (Y/N)? y
Will SATURN be a satellite [Y]? N
Will SATURN be a boot server [Y]? n

This procedure will now ask you for the device name of SATURN’s system root. The default device name (DISK$BIG_X5T5:) is the logical volume name of SYS$SYSDEVICE:.

What is the device name for SATURN’s system root [DISK$BIG_X5T5:]?
What is the name of SATURN’s system root [SYS10]? SYS2
Creating directory tree SYS2 ...
System root SYS2 created

NOTE:
All nodes on the same SCSI bus must be members of the same cluster and must all have the same non-zero disk allocation class or each will have a different name for the same disk and data corruption will result.

Enter a value for SATURN’s ALLOCLASS parameter [7]:

A.7.2 Error Reports and OPCOM Messages in Multihost SCSI Environments

Certain common operations, such as booting or shutting down a host on a multihost SCSI bus, can cause other hosts on the SCSI bus to experience errors. In addition, certain errors that are unusual in a single-host SCSI configuration may occur more frequently on a multihost SCSI bus.

These errors are transient errors that OpenVMS detects, reports, and recovers from without losing data or affecting applications that are running. This section describes the conditions that generate these errors and the messages that are displayed on the operator console and entered into the error log.
SCSI as an OpenVMS Cluster Interconnect
A.7 Supplementary Information

A.7.2.1 SCSI Bus Resets
When a host connected to a SCSI bus first starts, either by being turned on or by rebooting, it does not know the state of the SCSI bus and the devices on it. The ANSI SCSI standard provides a method called BUS RESET to force the bus and its devices into a known state. A host typically asserts a RESET signal one or more times on each of its SCSI buses when it first starts up and when it shuts down. While this is a normal action on the part of the host asserting RESET, other hosts consider this RESET signal an error because RESET requires that the hosts abort and restart all I/O operations that are in progress.

A host may also reset the bus in the midst of normal operation if it detects a problem that it cannot correct in any other way. These kinds of resets are uncommon, but they occur most frequently when something on the bus is disturbed. For example, an attempt to hot plug a SCSI device while the device is still active (see Section A.7.6) or halting one of the hosts with Ctrl/P can cause a condition that forces one or more hosts to issue a bus reset.

A.7.2.2 SCSI Timeouts
When a host exchanges data with a device on the SCSI bus, there are several different points where the host must wait for the device or the SCSI adapter to react. In an OpenVMS system, the host is allowed to do other work while it is waiting, but a timer is started to make sure that it does not wait too long. If the timer expires without a response from the SCSI device or adapter, this is called a timeout.

There are three kinds of timeouts:

• Disconnect timeout—The device accepted a command from the host and disconnected from the bus while it processed the command but never reconnected to the bus to finish the transaction. This error happens most frequently when the bus is very busy. See Section A.7.5 for more information. The disconnect timeout period varies with the device, but for most disks, it is about 20 seconds.

• Selection timeout—The host tried to send a command to a device on the SCSI bus, but the device did not respond. This condition might happen if the device did not exist or if it were removed from the bus or powered down. (This failure is not more likely with a multi-initiator system; it is mentioned here for completeness.) The selection timeout period is about 0.25 seconds.

• Interrupt timeout—The host expected the adapter to respond for any other reason, but it did not respond. This error is usually an indication of a busy SCSI bus. It is more common if you have initiator unit numbers set low (0 or 1) rather than high (6 or 7). The interrupt timeout period is about 4 seconds.

Timeout errors are not inevitable on SCSI OpenVMS Cluster systems. However, they are more frequent on SCSI buses with heavy traffic and those with two initiators. They do not necessarily indicate a hardware or software problem. If they are logged frequently, you should consider ways to reduce the load on the SCSI bus (for example, adding an additional bus).
A.7.2.3 Mount Verify

Mount verify is a condition declared by a host about a device. The host declares this condition in response to a number of possible transient errors, including bus resets and timeouts. When a device is in the mount verify state, the host suspends normal I/O to it until the host can determine that the correct device is there, and that the device is accessible. Mount verify processing then retries outstanding I/Os in a way that insures that the correct data is written or read. Application programs are unaware that a mount verify condition has occurred as long as the mount verify completes.

If the host cannot access the correct device within a certain amount of time, it declares a mount verify timeout, and application programs are notified that the device is unavailable. Manual intervention is required to restore a device to service after the host has declared a mount verify timeout. A mount verify timeout usually means that the error is not transient. The system manager can choose the timeout period for mount verify; the default is one hour.

A.7.2.4 Shadow Volume Processing

Shadow volume processing is a process similar to mount verify, but it is for shadow set members. An error on one member of a shadow set places the set into the volume processing state, which blocks I/O while OpenVMS attempts to regain access to the member. If access is regained before shadow volume processing times out, then the outstanding I/Os are reissued and the shadow set returns to normal operation. If a timeout occurs, then the failed member is removed from the set. The system manager can select one timeout value for the system disk shadow set, and one for application shadow sets. The default value for both timeouts is 20 seconds.

Note

The SCSI disconnect timeout and the default shadow volume processing timeout are the same. If the SCSI bus is heavily utilized so that disconnect timeouts may occur, it may be desirable to increase the value of the shadow volume processing timeout. (A recommended value is 60 seconds.) This may prevent shadow set members from being expelled when they experience disconnect timeout errors.

A.7.2.5 Expected OPCOM Messages in Multihost SCSI Environments

When a bus reset occurs, an OPCOM message is displayed as each mounted disk enters and exits mount verification or shadow volume processing.

When an I/O to a drive experiences a timeout error, an OPCOM message is displayed as that drive enters and exits mount verification or shadow volume processing.

If a quorum disk on the shared SCSI bus experiences either of these errors, then additional OPCOM messages may appear, indicating that the connection to the quorum disk has been lost and regained.
A.7 Supplementary Information

A.7.2.6 Error Log Basics

In the OpenVMS system, the Error Log utility allows device drivers to save information about unusual conditions that they encounter. In the past, most of these unusual conditions have happened as a result of errors such as hardware failures, software failures, or transient conditions (for example, loose cables).

If you type the DCL command SHOW ERROR, the system displays a summary of the errors that have been logged since the last time the system booted. For example:

$ SHOW ERROR

<table>
<thead>
<tr>
<th>Device</th>
<th>Error Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>SALT$PKB0:</td>
<td>6</td>
</tr>
<tr>
<td>$1$DKB500:</td>
<td>10</td>
</tr>
<tr>
<td>PEA0:</td>
<td>1</td>
</tr>
<tr>
<td>SALT$PKA0:</td>
<td>9</td>
</tr>
<tr>
<td>$1$DKA0:</td>
<td>0</td>
</tr>
</tbody>
</table>

In this case, 6 errors have been logged against host SALT's SCSI port B (PKB0), 10 have been logged against disk $1$DKB500, and so forth.

To see the details of these errors, you can use the command ANALYZE/ERROR/SINCE=dd-mmm-yyyy:hh:mm:ss at the DCL prompt. The output from this command displays a list of error log entries with information similar to the following:

```
******************************* ENTRY 2337. *******************************
ERROR SEQUENCE 6. LOGGED ON: CPU_TYPE 00000002
DATE/TIME 29-MAY-1995 16:31:19.79 SYS_TYPE 0000000D
<identification information>
ERROR TYPE 03 COMMAND TRANSMISSION FAILURE
SCSI ID 01 SCSI ID = 1.
SCSI LUN 00 SCSI LUN = 0.
SCSI SUBLUN 00 SCSI SUBLUN = 0.
PORT STATUS 00000E32 %SYSTEM-E-RETRY, RETRY OPERATION
<additional information>
```

For this discussion, the key elements are the ERROR TYPE and, in some instances, the PORT STATUS fields. In this example, the error type is 03, COMMAND TRANSMISSION FAILURE, and the port status is 00000E32, SYSTEM-E-RETRY.

A.7.2.7 Error Log Entries in Multihost SCSI Environments

The error log entries listed in this section are likely to be logged in a multihost SCSI configuration, and you usually do not need to be concerned about them. You should, however, examine any error log entries for messages other than those listed in this section.

- **ERROR TYPE 0007, BUS RESET DETECTED**
  Occurs when the other system asserts the SCSI bus reset signal. This happens when:
  - A system's power-up self-test runs.
A console INIT command is executed.
- The EISA Configuration Utility (ECU) is run.
- The console BOOT command is executed (in this case, several resets occur).
- System shutdown completes.
- The system detects a problem with an adapter or a SCSI bus (for example, an interrupt timeout).

This error causes all mounted disks to enter mount verification.

• ERROR TYPE 05, EXTENDED SENSE DATA RECEIVED
When a SCSI bus is reset, an initiator must get “sense data” from each device. When the initiator gets this data, an EXTENDED SENSE DATA RECEIVED error is logged. This is expected behavior.

• ERROR TYPE 03, COMMAND TRANSMISSION FAILURE
PORT STATUS E32, SYSTEM-E-RETRY
Occasionally, one host may send a command to a disk while the disk is exchanging error information with the other host. Many disks respond with a SCSI “BUSY” code. The OpenVMS system responds to a SCSI BUSY code by logging this error and retrying the operation. You are most likely to see this error when the bus has been reset recently. This error does not always happen near resets, but when it does, the error is expected and unavoidable.

• ERROR TYPE 204, TIMEOUT
An interrupt timeout has occurred (see Section A.7.2.2). The disk is put into mount verify when this error occurs.

• ERROR TYPE 104, TIMEOUT
A selection timeout has occurred (see Section A.7.2.2). The disk is put into mount verify when this error occurs.

A.7.3 Restrictions and Known Problems

The OpenVMS Cluster software has the following restrictions when multiple hosts are configured on the same SCSI bus:

• For versions prior to OpenVMS Alpha Version 7.2, a node's access to a disk will not fail over from a direct SCSI path to an MSCP served path. There is also no failover from an MSCP served path to a direct SCSI path. Normally, this type of failover is not a consideration, because when OpenVMS discovers both a direct and a served path, it chooses the direct path permanently. However, you must avoid situations in which the MSCP served path becomes available first and is selected by OpenVMS before the direct path becomes available. To avoid this situation, observe the following rules:
  - A node that has a direct path to a SCSI system disk must boot the disk directly from the SCSI port, not over the LAN.
  - If a node is running the MSCP server, then a SCSI disk must not be added to the multihost SCSI bus after a second node boots (either by physically inserting it or by reconfiguring an HSZxx).
If you add a device after two nodes boot and then configure the device using SYSMAN, the device might become visible to one of the systems through the served path before the direct path is visible. Depending upon the timing of various events, this problem can sometimes be avoided by using the following procedure:

```sh
$ MCR SYSMAN
SYSMAN> SET ENVIRONMENT/CLUSTER
SYSMAN> IO AUTOCONFIGURE
```

To ensure that the direct path to a new device is used (including HSZxx virtual devices), reboot each node after a device is added.

- For versions prior to OpenVMS Alpha Version 7.2, if there are two paths to a device, the $DEVICE_SCAN system service and the F$DEVICE lexical function list each device on a shared bus twice. Devices on the shared bus are also listed twice in the output from the DCL command SHOW DEVICE if you boot a non-SCSI system disk. These double listings are errors in the display programs. They do not indicate a problem or imply that the MSCP served path is being used instead of the direct SCSI path.

- When a system powers up, boots, or shuts down, it resets the SCSI bus. These resets cause other hosts on the SCSI bus to experience I/O errors. For Files-11 volumes, the Mount Verification facility automatically recovers from these errors and completes the I/O. As a result, the user’s process continues to run without error.

  This level of error recovery is not possible for volumes that are mounted with the /FOREIGN qualifier. Instead, the user’s process receives an I/O error notification if it has I/O outstanding when a bus reset occurs.

  If possible, avoid mounting foreign devices on multihost SCSI buses. If foreign devices are mounted on the shared bus, make sure that systems on that bus do not assert a SCSI bus reset while I/O is being done to foreign devices.

- When the ARC console is enabled on a multihost SCSI bus, it sets the SCSI target ID for all local host adapters to 7. This setting causes a SCSI ID conflict if there is already a host or device on a bus at ID 7. A conflict of this type typically causes the bus, and possibly all the systems on the bus, to hang.

  The ARC console is used to access certain programs, such as the KZPSA configuration utilities. If you must run the ARC console, first disconnect the system from multihost SCSI buses and from buses that have a device at SCSI ID 7.

- Any SCSI bus resets that occur when a system powers up, boots, or shuts down cause other systems on the SCSI bus to log errors and display OPCOM messages. This is expected behavior and does not indicate a problem.

- Abruptly halting a system on a multihost SCSI bus (for example, by pressing Ctrl/P on the console) may leave the KZPAA SCSI adapter in a state that can interfere with the operation of the other host on the bus. You should initialize, boot, or continue an abruptly halted system as soon as possible after it has been halted.

- All I/O to a disk drive must be stopped while its microcode is updated. This typically requires more precautions in a multihost environment than are needed in a single-host environment. Refer to Section A.7.6.3 for the necessary procedures.
• The EISA Configuration Utility (ECU) causes a large number of SCSI bus resets. These resets cause the other system on the SCSI bus to pause while its I/O subsystem recovers. It is suggested (though not required) that both systems on a shared SCSI bus be shut down when the ECU is run.

OpenVMS Cluster systems also place one restriction on the SCSI quorum disk, whether the disk is located on a single-host SCSI bus or a multihost SCSI bus. The SCSI quorum disk must support tagged command queuing (TCQ). This is required because of the special handling that quorum I/O receives in the OpenVMS SCSI drivers.

This restriction is not expected to be significant, because all disks on a multihost SCSI bus must support tagged command queuing (see Section A.7.7), and because quorum disks are normally not used on single-host buses.

A.7.4 Troubleshooting

The following sections describe troubleshooting tips for solving common problems in an OpenVMS Cluster system that uses a SCSI interconnect.

A.7.4.1 Termination Problems

Verify that two terminators are on every SCSI interconnect (one at each end of the interconnect). The BA350 enclosure, the BA356 enclosure, the DWZZx, and the KZxxx adapters have internal terminators that are not visible externally (see Section A.4.4.)

A.7.4.2 Booting or Mounting Failures Caused by Incorrect Configurations

OpenVMS automatically detects configuration errors described in this section and prevents the possibility of data loss that could result from such configuration errors, either by bugchecking or by refusing to mount a disk.

A.7.4.2.1 Bugchecks During the Bootstrap Process

For versions prior to OpenVMS Alpha Version 7.2, there are three types of configuration errors that can cause a bugcheck during booting. The bugcheck code is VAXCLUSTER, Error detected by OpenVMS Cluster software.

When OpenVMS boots, it determines which devices are present on the SCSI bus by sending an inquiry command to every SCSI ID. When a device receives the inquiry, it indicates its presence by returning data that indicates whether it is a disk, tape, or processor.

Some processor devices (host adapters) answer the inquiry without assistance from the operating system; others require that the operating system be running. The adapters supported in OpenVMS Cluster systems require the operating system to be running. These adapters, with the aid of OpenVMS, pass information in their response to the inquiry that allows the recipient to detect the following configuration errors:

• Different controller device names on the same SCSI bus

Unless a port allocation class is being used, the OpenVMS device name of each adapter on the SCSI bus must be identical (for example, all named PKC0). Otherwise, the OpenVMS Cluster software cannot coordinate the host's accesses to storage (see Section A.6.2 and Section A.6.3).

OpenVMS can check this automatically because it sends the controller letter in the inquiry response. A booting system receives this response, and it compares the remote controller letter with the local controller letter. If a mismatch is detected, then an OPCOM message is printed, and the system stops with a VAXCLUSTER bugcheck to prevent the possibility of data
loss. See the description of the NOMATCH error in the Help Message utility. (To use the Help Message utility for NOMATCH, enter HELP/MESSAGE NOMATCH at the DCL prompt.)

- Different or zero allocation class values.
  Each host on the SCSI bus must have the same nonzero disk allocation class value, or matching port allocation class values. Otherwise, the OpenVMS Cluster software cannot coordinate the host’s accesses to storage (see Section A.6.2 and Section A.6.3).
  OpenVMS is able to automatically check this, because it sends the needed information in the inquiry response. A booting system receives this response, and compares the remote value with the local value. If a mismatch or a zero value is detected, then an OPCOM message is printed, and the system stops with a VAXCLUSTER bugcheck to prevent the possibility of data loss. See the description of the ALLODIFF and ALLOZERO errors in the Help Message utility.

- Unsupported processors
  There may be processors on the SCSI bus that are not running OpenVMS or that do not return the controller name or allocation class information needed to validate the configuration. If a booting system receives an inquiry response and the response does not contain the special OpenVMS configuration information, then an OPCOM message is printed and an VAXCLUSTER bugcheck occurs. See the description of the CPUNOTSUP error in the Help Message utility.
  If your system requires the presence of a processor device on a SCSI bus, then refer to the CPUNOTSUP message description in the Help Message utility for instructions on the use of a special SYSGEN parameter, SCSICLUSTER_Pn for this case.

A.7.4.2.2 Failure to Configure Devices
In OpenVMS Alpha Version 7.2, SCSI devices on a misconfigured bus (as described in Section A.7.4.2.1) are not configured. Instead, error messages that describe the incorrect configuration are displayed.

A.7.4.2.3 Mount Failures
There are two types of configuration error that can cause a disk to fail to mount.

First, when a system boots from a disk on the shared SCSI bus, it may fail to mount the system disk. This happens if there is another system on the SCSI bus that is already booted, and the other system is using a different device name for the system disk. (Two systems will disagree about the name of a device on the shared bus if their controller names or allocation classes are misconfigured, as described in the previous section.) If the system does not first execute one of the bugchecks described in the previous section, then the following error message is displayed on the console:

%SYSINIT-E- error when mounting system device, retrying..., status = 007280B4

The decoded representation of this status is:

VOLALRMNT, another volume of same label already mounted

This error indicates that the system disk is already mounted in what appears to be another drive in the OpenVMS Cluster system, so it is not mounted again. To solve this problem, check the controller letters and allocation class values for each node on the shared SCSI bus.
Second, SCSI disks on a shared SCSI bus will fail to mount on both systems unless the disk supports tagged command queuing (TCQ). This is because TCQ provides a command-ordering guarantee that is required during OpenVMS Cluster state transitions.

OpenVMS determines that another processor is present on the SCSI bus during autoconfiguration, using the mechanism described in Section A.7.4.2.1. The existence of another host on a SCSI bus is recorded and preserved until the system reboots.

This information is used whenever an attempt is made to mount a non-TCQ device. If the device is on a multihost bus, the mount attempt fails and returns the following message:

%MOUNT-F-DRVERR, fatal drive error.

If the drive is intended to be mounted by multiple hosts on the same SCSI bus, then it must be replaced with one that supports TCQ.

Note that the first processor to boot on a multihost SCSI bus does not receive an inquiry response from the other hosts because the other hosts are not yet running OpenVMS. Thus, the first system to boot is unaware that the bus has multiple hosts, and it allows non-TCQ drives to be mounted. The other hosts on the SCSI bus detect the first host, however, and they are prevented from mounting the device. If two processors boot simultaneously, it is possible that they will detect each other, in which case neither is allowed to mount non-TCQ drives on the shared bus.

A.7.4.3 Grounding

Having excessive ground offset voltages or exceeding the maximum SCSI interconnect length can cause system failures or degradation in performance. See Section A.7.8 for more information about SCSI grounding requirements.

A.7.4.4 Interconnect Lengths

Adequate signal integrity depends on strict adherence to SCSI bus lengths. Failure to follow the bus length recommendations can result in problems (for example, intermittent errors) that are difficult to diagnose. See Section A.4.3 for information on SCSI bus lengths.

A.7.5 SCSI Arbitration Considerations

Only one initiator (typically, a host system) or target (typically, a peripheral device) can control the SCSI bus at any one time. In a computing environment where multiple targets frequently contend for access to the SCSI bus, you could experience throughput issues for some of these targets. This section discusses control of the SCSI bus, how that control can affect your computing environment, and what you can do to achieve the most desirable results.

Control of the SCSI bus changes continually. When an initiator gives a command (such as READ) to a SCSI target, the target typically disconnects from the SCSI bus while it acts on the command, allowing other targets or initiators to use the bus. When the target is ready to respond to the command, it must regain control of the SCSI bus. Similarly, when an initiator wishes to send a command to a target, it must gain control of the SCSI bus.

If multiple targets and initiators want control of the bus simultaneously, bus ownership is determined by a process called arbitration, defined by the SCSI standard. The default arbitration rule is simple: control of the bus is given to the requesting initiator or target that has the highest unit number.
The following sections discuss some of the implications of arbitration and how you can respond to arbitration situations that affect your environment.

A.7.5.1 Arbitration Issues in Multiple-Disk Environments

When the bus is not very busy, and bus contention is uncommon, the simple arbitration scheme is adequate to perform I/O requests for all devices on the system. However, as initiators make more and more frequent I/O requests, contention for the bus becomes more and more common. Consequently, targets with lower ID numbers begin to perform poorly, because they are frequently blocked from completing their I/O requests by other users of the bus (in particular, targets with the highest ID numbers). If the bus is sufficiently busy, low-numbered targets may never complete their requests. This situation is most likely to occur on systems with more than one initiator because more commands can be outstanding at the same time.

The OpenVMS system attempts to prevent low-numbered targets from being completely blocked by monitoring the amount of time an I/O request takes. If the request is not completed within a certain period, the OpenVMS system stops sending new requests until the tardy I/Os complete. While this algorithm does not ensure that all targets get equal access to the bus, it does prevent low-numbered targets from being totally blocked.

A.7.5.2 Solutions for Resolving Arbitration Problems

If you find that some of your disks are not being serviced quickly enough during periods of heavy I/O, try some or all of the following, as appropriate for your site:

- Obtain the DWZZH–05 SCSI hub and enable its fair arbitration feature.
- Assign the highest ID numbers to those disks that require the fastest response time.
- Spread disks across more SCSI buses.
- Keep disks that need to be accessed only by a single host (for example, page and swap disks) on a nonshared SCSI bus.

Another method that might provide for more equal servicing of lower and higher ID disks is to set the host IDs to the lowest numbers (0 and 1) rather than the highest. When you use this method, the host cannot gain control of the bus to send new commands as long as any disk, including those with the lowest IDs, need the bus. Although this option is available to improve fairness under some circumstances, this configuration is less desirable in most instances, for the following reasons:

- It can result in lower total throughput.
- It can result in timeout conditions if a command cannot be sent within a few seconds.
- It can cause physical configuration difficulties. For example, StorageWorks shelves such as the BA350 have no slot to hold a disk with ID 7, but they do have a slot for a disk with ID 0. If you change the host to ID 0, you must remove a disk from slot 0 in the BA350, but you cannot move the disk to ID 7. If you have two hosts with IDs 0 and 1, you cannot use slot 0 or 1 in the BA350. (Note, however, that you can have a disk with ID 7 in a BA353.)
A.7.5.3 Arbitration and Bus Isolators

Any active device, such as a DWZZx, that connects bus segments introduces small delays as signals pass through the device from one segment to another. Under some circumstances, these delays can be another cause of unfair arbitration. For example, consider the following configuration, which could result in disk servicing problems (starvation) under heavy work loads:

![Diagram of disk configuration]

Although disk 5 has the highest ID number, there are some circumstances under which disk 5 has the lowest access to the bus. This can occur after one of the lower-numbered disks has gained control of the bus and then completed the operation for which control of the bus was needed. At this point, disk 5 does not recognize that the bus is free and might wait before trying to arbitrate for control of the bus. As a result, one of the lower-numbered disks, having become aware of the free bus and then submitting a request for the bus, will gain control of the bus.

If you see this type of problem, the following suggestions can help you reduce its severity:

- Try to place all disks on the same bus segment.
- If placing all disks on the same bus segment is not possible (for example if you have both some RZ28 disks by themselves and an HSZxx, try to use a configuration that has only one isolator between any pair of disks.
- If your configuration requires two isolators between a pair of disks (for example, to meet distance requirements), try to balance the number of disks on each bus segment.
- Follow the suggestions in Section A.7.5.2 to reduce the total traffic on the logical bus.

A.7.6 Removal and Insertion of SCSI Devices While the OpenVMS Cluster System is Operating

With proper procedures, certain SCSI devices can be removed from or inserted onto an active SCSI bus without disrupting the ongoing operation of the bus. This capability is referred to as hot plugging. Hot plugging can allow a suitably configured OpenVMS Cluster system to continue to run while a failed component is replaced. Without hot plugging, it is necessary to make the SCSI bus inactive and remove power from all the devices on the SCSI bus before any device is removed from it or inserted onto it.

In a SCSI OpenVMS Cluster system, hot plugging requires that all devices on the bus have certain electrical characteristics and be configured appropriately on the SCSI bus. Successful hot plugging also depends on strict adherence to the procedures described in this section. These procedures ensure that the hot-plugged device is inactive and that active bus signals are not disturbed.
This section describes hot-plugging procedures for devices that are on the same SCSI bus as the host that is running OpenVMS. The procedures are different for SCSI buses that are behind a storage controller, such as the HSZxx. Refer to the storage controller documentation for the procedures to hot plug devices that they control.

A.7.6.1 Terminology for Describing Hot Plugging

The terms shown in bold in this section are used in the discussion of hot plugging rules and procedures.

- A SCSI bus segment consists of two terminators, the electrical path forming continuity between them, and possibly, some attached stubs. Bus segments can be connected together by bus isolators (for example, DWZZx), to form a logical SCSI bus or just a SCSI bus.
- There are two types of connections on a segment: bussing connections, which break the path between two terminators, and stubbing connections, which disconnect all or part of a stub.
- A device is active on the SCSI bus when it is asserting one or more of the bus signals. A device is inactive when it is not asserting any bus signals. The segment attached to a bus isolator is inactive when all devices on that segment, except possibly the bus isolator, are inactive.
- A port on a bus isolator has proper termination when it is attached to a segment that is terminated at both ends and has TERMPWR in compliance with SCSI-2 requirements.

A.7.6.2 Rules for Hot Plugging

Follow these rules when planning for and performing hot plugging:

- The device to be hot plugged, and all other devices on the same segment, must meet the electrical requirements described in Annex A, Section A.4, of the SCSI-3 Parallel Interface (SPI) Standard, working draft X3T10/855D. Referring to this draft standard is necessary because the SCSI-2 standard does not adequately specify the requirements for hot plugging. The SPI document places requirements on the receivers and terminators on the segment where the hot plugging is being performed, and on the transceivers, TERMPWR, termination, and power/ground/signal sequencing, of the device that is being hot plugged.
- Hot plugging must occur only at a stubbing connection.
  This implies that a hot-plugged device can make only one connection to the SCSI bus, the device must not provide termination for the SCSI bus, and the device’s connection must not exceed the maximum stub length, as shown in Figure A–3. An example of a SCSI bus topology showing the valid hot plugging connections is illustrated in Figure A–13.
- Take precautions to ensure that electrostatic discharge (ESD) does not damage devices or disrupt active signals on the SCSI bus. You should take such precautions during the process of disconnecting and connecting, as well as during the time that SCSI bus conductors are exposed.
• Take precaution to ensure that ground offset voltages do not pose a safety hazard and will not interfere with SCSI bus signaling, especially in single-ended configurations. The procedures for measuring and eliminating ground offset voltages are described in Section A.7.8.

• The device that is hot plugged must be inactive during the disconnection and connection operations. Otherwise, the SCSI bus may hang. OpenVMS will eventually detect a hung bus and reset it, but this problem may first temporarily disrupt OpenVMS Cluster operations.

____________________ Note ______________________

Ideally, a device will also be inactive whenever its power is removed, for the same reason.

The procedures for ensuring that a device is inactive are described in Section A.7.6.3.

• A quorum disk must not be hot plugged. This is because there is no mechanism for stopping the I/O to a quorum disk, and because the replacement disk will not contain the correct quorum file.

The OpenVMS Cluster system must be reconfigured to remove a device as a quorum disk before that device is removed from the bus. The procedure for accomplishing this is described in OpenVMS Cluster Systems.

An alternate method for increasing the availability of the quorum disk is to use an HSZxx mirror set as the quorum disk. This would allow a failed member to be replaced while maintaining the quorum disk functionality.
• Disks must be dismounted logically before removing or replacing them in a hot-plugging operation. This is required to ensure that the disk is inactive and to ensure the integrity of the file system.

• The DWZZx must be powered up when it is inserted into an active SCSI bus and should remain powered up at all times while it is attached to the active SCSI bus. This is because the DWZZx can disrupt the operation of the attached segments when it is powering up or down.

• The segment attached to a bus isolator must be maintained in the inactive state whenever the other port on the bus isolator is terminated improperly. This is required because an improperly terminated bus isolator port may pass erroneous signals to the other port.

Thus, for a particular hot-plugging operation, one of the segments attached to a bus isolator must be designated as the (potentially) active segment, and the other must be maintained in the inactive state, as illustrated in Figure A–14. The procedures for ensuring that a segment is inactive are described in Section A.7.6.3.

Figure A–14 Hot Plugging a Bus Isolator

![Diagram showing hot plugging a bus isolator](image)

Note that, although a bus isolator may have more than one stubbing connection and thus be capable of hot plugging on each of them, only one segment can be the active segment for any particular hot-plugging operation.

• Take precautions to ensure that the only electrical conductor that contacts a connector pin is its mate. These precautions must be taken during the process of disconnecting and connecting as well as during the time the connector is disconnected.

• Devices must be replaced with devices of the same type. That is, if any system in the OpenVMS Cluster configures a SCSI ID as a DK or MK device, then that SCSI ID must contain only DK or MK devices, respectively, for as long as that OpenVMS Cluster member is running.

Different implementations of the same device type can be substituted (for example, an RZ26L can be replaced with an RZ28B). Note that the system will not recognize the change in device type until an attempt is made to mount the new device. Also, note that host-based shadowing continues to require that all members of a shadow set be the same device type.
• SCSI IDs that are empty when a system boots must remain empty as long as that system is running. This rule applies only if there are multiple processors on the SCSI bus and the MSCP server is loaded on any of them. (The MSCP server is loaded when the MSCP_LOAD system parameter is set to 1).

This is required to ensure that nodes on the SCSI bus use their direct path to the disk rather than the served path. When the new device is configured on a system (using SYSMAN IO commands), that system serves it to the second system on the shared SCSI bus. The second system automatically configures the new device by way of the MSCP served path. Once this occurs, the second system will be unable to use its direct SCSI path to the new device because failover from an MSCP served path to a direct SCSI path is not implemented.

A.7.6.3 Procedures for Ensuring That a Device or Segment is Inactive

Use the following procedures to ensure that a device or a segment is inactive:

• To ensure that a disk is inactive:
  1. Dismount the disk on all members of the OpenVMS Cluster system.
  2. Ensure that any I/O that can occur to a dismounted disk is stopped, for example:
     - Disable the disk as a quorum disk.
     - Allocate the disk (using the DCL command ALLOCATE) to block further mount or initialization attempts.
     - Disable console polling by all halted hosts on the logical SCSI bus (by setting the console variable SCSI POLL to OFF and entering the INIT command).
     - Ensure that no host on the logical SCSI bus is executing power-up or initialization self-tests, booting, or configuring the SCSI bus (using SYSMAN IO commands).

• To ensure that an HSZxx controller is inactive:
  1. Dismount all of the HSZxx virtual disks on all members of the OpenVMS Cluster system.
  2. Shut down the controller, following the procedures in the HS Family of Array Controllers User's Guide.
  3. Power down the HSZxx (optional).

• To ensure that a host adapter is inactive:
  1. Halt the system.
  2. Power down the system, or set the console variable SCSI POLL to OFF and then enter the INIT command on the halted system. This ensures that the system will not poll or respond to polls.

• To ensure that a segment is inactive, follow the preceding procedures for every device on the segment.
A.7.6.4 Procedure for Hot Plugging StorageWorks SBB Disks

To remove an SBB (storage building block) disk from an active SCSI bus, use the following procedure:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance.
2. Follow the procedure in Section A.7.6.3 to make the disk inactive.
3. Squeeze the clips on the side of the SBB, and slide the disk out of the StorageWorks shelf.

To plug an SBB disk into an active SCSI bus, use the following procedure:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance.
2. Ensure that the SCSI ID associated with the device (either by jumpers or by the slot in the StorageWorks shelf) conforms to the following:
   - The SCSI ID is unique for the logical SCSI bus.
   - The SCSI ID is already configured as a DK device on all of the following:
     - Any member of the OpenVMS Cluster system that already has that ID configured
     - Any OpenVMS processor on the same SCSI bus that is running the MSCP server
3. Slide the SBB into the StorageWorks shelf.
4. Configure the disk on OpenVMS Cluster members, if required, using SYSMAN IO commands.

A.7.6.5 Procedure for Hot Plugging HSZxx

To remove an HSZxx controller from an active SCSI bus:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance.
2. Follow the procedure in Section A.7.6.3 to make the HSZxx inactive.
3. The HSZxx can be powered down, but it must remain plugged in to the power distribution system to maintain grounding.
4. Unscrew and remove the differential triconnector from the HSZxx.
5. Protect all exposed connector pins from ESD and from contacting any electrical conductor while they are disconnected.

To plug an HSZxx controller into an active SCSI bus:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance. Also, ensure that the ground offset voltages between the HSZxx and all components that will be attached to it are within the limits specified in Section A.7.8.
2. Protect all exposed connector pins from ESD and from contacting any electrical conductor while they are disconnected.
3. Power up the HSZxx and ensure that the disk units associated with the HSZxx conform to the following:
   • The disk units are unique for the logical SCSI bus.
   • The disk units are already configured as DK devices on the following:
     – Any member of the OpenVMS Cluster system that already has that ID configured
     – Any OpenVMS processor on the same SCSI bus that is running the MSCP server

4. Ensure that the HSZxx will make a legal stubbing connection to the active segment. (The connection is legal when the triconnector is attached directly to the HSZxx controller module, with no intervening cable.)

5. Attach the differential triconnector to the HSZxx, using care to ensure that it is properly aligned. Tighten the screws.

6. Configure the HSZxx virtual disks on OpenVMS Cluster members, as required, using SYSMAN IO commands.

A.7.6.6 Procedure for Hot Plugging Host Adapters

To remove a host adapter from an active SCSI bus:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance.

2. Verify that the connection to be broken is a stubbing connection. If it is not, then do not perform the hot plugging procedure.

3. Follow the procedure in Section A.7.6.3 to make the host adapter inactive.

4. The system can be powered down, but it must remain plugged in to the power distribution system to maintain grounding.

5. Remove the “Y” cable from the host adapter’s single-ended connector.

6. Protect all exposed connector pins from ESD and from contacting any electrical conductor while they are disconnected.

7. Do not unplug the adapter from the host’s internal bus while the host remains powered up.
   At this point, the adapter has disconnected from the SCSI bus. To remove the adapter from the host, first power down the host, then remove the adapter from the host’s internal bus.

To plug a host adapter into an active SCSI bus:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance. Also, ensure that the ground offset voltages between the host and all components that will be attached to it are within the limits specified in Section A.7.8.

2. Protect all exposed connector pins from ESD and from contacting any electrical conductor while they are disconnected.

3. Ensure that the host adapter will make a legal stubbing connection to the active segment (the stub length must be within allowed limits, and the host adapter must not provide termination to the active segment).
4. Plug the adapter into the host (if it is unplugged).
5. Plug the system into the power distribution system to ensure proper grounding. Power up, if desired.
6. Attach the "Y" cable to the host adapter, using care to ensure that it is properly aligned.

A.7.6.7 Procedure for Hot Plugging DWZZx Controllers

Use the following procedure to remove a DWZZx from an active SCSI bus:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance.
2. Verify that the connection to be broken is a stubbing connection. If it is not, then do not perform the hot plugging procedure.
3. Do not power down the DWZZx. This can disrupt the operation of the attached SCSI bus segments.
4. Determine which SCSI bus segment will remain active after the disconnection. Follow the procedure in Section A.7.6.3 to make the other segment inactive.

When the DWZZx is removed from the active segment, the inactive segment must remain inactive until the DWZZx is also removed from the inactive segment, or until proper termination is restored to the DWZZx port that was disconnected from the active segment.
5. The next step depends on the type of DWZZx and the segment that is being hot plugged, as follows:

<table>
<thead>
<tr>
<th>DWZZx Type</th>
<th>Condition</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBB¹</td>
<td>Single-ended segment will remain active.</td>
<td>Squeeze the clips on the side of the SBB, and slide the DWZZx out of the StorageWorks shelf.</td>
</tr>
<tr>
<td>SBB¹</td>
<td>Differential segment will remain active.</td>
<td>Unscrew and remove the differential triconnector from the DWZZx.</td>
</tr>
<tr>
<td>Table top</td>
<td>Single-ended segment will remain active.</td>
<td>Remove the &quot;Y&quot; cable from the DWZZx’s single-ended connector.</td>
</tr>
<tr>
<td>Table top</td>
<td>Differential segment will remain active.</td>
<td>Unscrew and remove the differential triconnector from the DWZZx.</td>
</tr>
</tbody>
</table>

¹SBB is the StorageWorks abbreviation for storage building block.

6. Protect all exposed connector pins from ESD and from contacting any electrical conductor while they are disconnected.

To plug a DWZZx into an active SCSI bus:

1. Use an ESD grounding strap that is attached either to a grounding stud or to unpainted metal on one of the cabinets in the system. Refer to the system installation procedures for guidance. Also, ensure that the ground offset voltages between the DWZZx and all components that will be attached to it are within the limits specified in Section A.7.8.
2. Protect all exposed connector pins from ESD and from contacting any electrical conductor while they are disconnected.
3. Ensure that the DWZZx will make a legal stubbing connection to the active segment (the stub length must be within allowed limits, and the DWZZx must not provide termination to the active segment).

4. The DWZZx must be powered up. The SCSI segment that is being added must be attached and properly terminated. All devices on this segment must be inactive.

5. The next step depends on the type of DWZZx, and which segment is being hot plugged, as follows:

<table>
<thead>
<tr>
<th>DWZZx Type</th>
<th>Condition</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBB¹</td>
<td>Single-ended segment is being hot plugged.</td>
<td>Slide the DWZZx into the StorageWorks shelf.</td>
</tr>
<tr>
<td>SBB¹</td>
<td>Differential segment is being hot plugged.</td>
<td>Attach the differential triconnector to the DWZZx, using care to ensure that it is properly aligned. Tighten the screws.</td>
</tr>
<tr>
<td>Table top</td>
<td>Single-ended segment is being hot plugged.</td>
<td>Attach the “Y” cable to the DWZZx, using care to ensure that it is properly aligned.</td>
</tr>
<tr>
<td>Table top</td>
<td>Differential segment is being hot plugged.</td>
<td>Attach the differential triconnector to the DWZZx, using care to ensure that it is properly aligned. Tighten the screws.</td>
</tr>
</tbody>
</table>

¹SSB is the StorageWorks abbreviation for storage building block.

6. If the newly attached segment has storage devices on it, then configure them on OpenVMS Cluster members, if required, using SYSMAN IO commands.

A.7.7 OpenVMS Requirements for Devices Used on Multihost SCSI OpenVMS Cluster Systems

At this time, the only devices approved for use on multihost SCSI OpenVMS Cluster systems are those listed in Table A–2. While not specifically approved for use, other disk devices might be used in a multihost OpenVMS Cluster system when they conform to the following requirements:

- Support for concurrent multi-initiator I/O.
- Proper management for the following states or conditions on a per-initiator basis:
  - Synchronous negotiated state and speed
  - Width negotiated state
  - Contingent Allegiance and Unit Attention conditions
- Tagged command queuing. This is needed to provide an ordering guarantee used in OpenVMS Cluster systems to ensure that I/O has been flushed. The drive must implement queuing that complies with Section 7.8.2 of the SCSI–2 standard, which says (in part):

  "...All commands received with a simple queue tag message prior to a command received with an ordered queue tag message, regardless of initiator, shall be executed before that command with the ordered queue tag message." (Emphasis added.)
Support for command disconnect.

A reselection timeout procedure compliant with Option b of Section 6.1.4.2 of the SCSI–2 standard. Furthermore, the device shall implement a reselection retry algorithm that limits the amount of bus time spent attempting to reselect a nonresponsive initiator.

Automatic read reallocation enabled (ARRE) and automatic write reallocation enabled (AWRE) (that is, drive-based bad block revectoring) to prevent multiple hosts from unnecessarily revectoring the same block. To avoid data corruption, it is essential that the drive comply with Section 9.3.3.6 of the SCSI–2 Standard, which says (in part):

“...The automatic reallocation shall then be performed only if the target successfully recovers the data.” (Emphasis added.)

Storage devices should not supply TERMPWR. If they do, then it is necessary to apply configuration rules to ensure that there are no more than four sources of TERMPWR on a segment.

Finally, if the device or any other device on the same segment will be hot plugged, then the device must meet the electrical requirements described in Section A.7.6.2.

A.7.8 Grounding Requirements

This section describes the grounding requirements for electrical systems in a SCSI OpenVMS Cluster system.

Improper grounding can result in voltage differentials, called ground offset voltages, between the enclosures in the configuration. Even small ground offset voltages across the SCSI interconnect (as shown in step 3 of Table A–8) can disrupt the configuration and cause system performance degradation or data corruption.

Table A–8 describes important considerations to ensure proper grounding.

<table>

(continued on next page)
Table A–8 (Cont.)  Steps for Ensuring Proper Grounding

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 3    | If you have difficulty verifying these conditions, you can use a hand-held multimeter to measure the ground offset voltage between any two cabinets. To measure the voltage, connect the multimeter leads to unpainted metal on each enclosure. Then determine whether the voltage exceeds the following allowable ground offset limits:  
  - Single-ended signaling: 50 millivolts (maximum allowable offset)  
  - Differential signaling: 800 millivolts (maximum allowable offset)  
  The multimeter method provides data for only the moment it is measured. The ground offset values may change over time as additional devices are activated or plugged into the same power source. To ensure that the ground offsets remain within acceptable limits over time, Compaq recommends that you have a power survey performed by a qualified electrician. |
| 4    | If you are uncertain about the grounding situation or if the measured offset exceeds the allowed limit, Compaq recommends that a qualified electrician correct the problem. It may be necessary to install grounding cables between enclosures to reduce the measured offset. |
| 5    | If an unacceptable offset voltage was measured and a ground cable was installed, then measure the voltage again to ensure it is less than the allowed limits. If not, an electrician must determine the source of the ground offset voltage and reduce or eliminate it. |
This appendix contains information about MEMORY CHANNEL, a high-performance cluster interconnect technology. MEMORY CHANNEL, which was introduced in OpenVMS Alpha Version 7.1, supports several configurations.

This chapter contains the following sections:

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Product Overview</td>
<td>High-level introduction to the MEMORY CHANNEL product and its benefits, hardware components, and configurations.</td>
</tr>
<tr>
<td>Technical Overview</td>
<td>More in-depth technical information about how MEMORY CHANNEL works.</td>
</tr>
</tbody>
</table>

**B.1 Product Overview**

MEMORY CHANNEL is a high-performance cluster interconnect technology for PCI-based Alpha systems. With the benefits of very low latency, high bandwidth, and direct memory access, MEMORY CHANNEL complements and extends the unique ability of an OpenVMS Cluster to work as a single, virtual system.

MEMORY CHANNEL offloads internode cluster traffic (such as lock management communication) from existing interconnects—CI, DSSI, FDDI, and Ethernet—so that they can process storage and network traffic more effectively. MEMORY CHANNEL significantly increases throughput and decreases the latency associated with traditional I/O processing.

Any application that must move large amounts of data among nodes will benefit from MEMORY CHANNEL. It is an optimal solution for applications that need to pass data quickly, such as real-time and transaction processing. MEMORY CHANNEL also improves throughput in high-performance databases and other applications that generate heavy OpenVMS Lock Manager traffic.

**B.1.1 MEMORY CHANNEL Features**

MEMORY CHANNEL technology provides the following features:

- **Offers excellent price/performance.**

  With several times the CI bandwidth, MEMORY CHANNEL provides a 100 MB/s interconnect with minimal latency. MEMORY CHANNEL architecture is designed for the industry-standard PCI bus.
B.1 Product Overview

- **Requires no change to existing applications.**
  MEMORY CHANNEL works seamlessly with existing cluster software, so that no change is necessary for existing applications. The new MEMORY CHANNEL drivers, PMDRIVER and MCDRIVER, integrate with the Systems Communication Services layer of OpenVMS Clusters in the same way as existing port drivers. Higher layers of cluster software are unaffected.

- **Offloads CI, DSSI, and the LAN in SCSI clusters.**
  You cannot connect storage directly to MEMORY CHANNEL. While MEMORY CHANNEL is not a replacement for CI and DSSI, when used in combination with those interconnects, it offloads their node-to-node traffic. This enables them to be dedicated to storage traffic, optimizing communications in the entire cluster.

- **Provides fail-separated behavior.**
  When a system failure occurs, MEMORY CHANNEL nodes behave like any failed node in an OpenVMS Cluster. The rest of the cluster continues to perform until the failed node can rejoin the cluster.

B.1.2 MEMORY CHANNEL Version 2.0 Features

When first introduced in OpenVMS Version 7.1, MEMORY CHANNEL supported a maximum of four nodes in a 10-foot radial topology. Communication occurred between one sender-receiver pair at a time. MEMORY CHANNEL Version 1.5 introduced support for eight nodes, a new adapter (CCMAA–BA), time stamps on all messages, and more robust performance.

MEMORY CHANNEL Version 2.0 provides the following new capabilities:

- Support for a new adapter (CCMAB-AA) and new hubs (CCMHB-AA and CCMHB-BA)
- Support for simultaneous communication between four sender-receiver pairs
- Support for longer cables for a radial topology up to 3 km

B.1.3 Hardware Components

A MEMORY CHANNEL cluster is joined together by a hub, a desktop-PC sized unit which provides a connection among systems. The hub is connected to a system’s PCI adapter by a link cable. Figure B–1 shows all three hardware components required by a node to support MEMORY CHANNEL:

- A PCI-to-MEMORY CHANNEL adapter
- A link cable
- A port in a MEMORY CHANNEL hub (except for a two-node configuration in which the cable connects just two PCI adapters.)
The PCI adapter pictured in Figure B–1 has memory mapping logic that enables each system to communicate with the others in the MEMORY CHANNEL cluster. Figure B–2 shows an example of a four-node MEMORY CHANNEL cluster with a hub at its center.
B.1 Product Overview

A MEMORY CHANNEL hub is not required in clusters that contain only two nodes. In a two-node configuration like the one shown Figure B–3, the same adapters and cable are used, and one of the PCI adapters serves as a virtual hub. You can continue to use the adapters and cable if you expand to a larger configuration later.

Figure B–3 Virtual Hub MEMORY CHANNEL Cluster

B.1.4 Backup Interconnect for High-Availability Configurations

MEMORY CHANNEL requires a central hub in configurations of three or more nodes. The MEMORY CHANNEL hub contains active, powered electronic components. In the event of a hub failure, resulting from either a power shutdown or component failure, the MEMORY CHANNEL interconnect ceases operation. This type of failure does not occur with the other cluster interconnects, such as CI, DSSI, and most LAN configurations.

Compaq therefore recommends that customers with MEMORY CHANNEL configurations who have high availability requirements consider using one of the following configurations to provide a second backup interconnect:

• In most cases a second interconnect can easily be configured by enabling the LAN (Ethernet or FDDI) for clustering. FDDI and 100 Mb/s Ethernet usually provide acceptable interconnect performance in the event of MEMORY CHANNEL failure. (See OpenVMS Cluster Systems and Guidelines for OpenVMS Cluster Configurations for details about how to enable the LAN for clustering.)

• CI and DSSI interconnects automatically act as a backup for MEMORY CHANNEL.

• A configuration with two MEMORY CHANNEL interconnects provides the highest possible performance as well as continued operation if one MEMORY CHANNEL interconnect fails.

B.1.5 Software Requirements

The use of MEMORY CHANNEL imposes certain requirements on memory and on your choice of diagnostic tools.

B.1.5.1 Memory Requirements

MEMORY CHANNEL consumes memory during normal operations. Each system in your MEMORY CHANNEL cluster must have at least 128 MB of memory.
B.1.5.2 Large-Memory Systems’ Use of NPAGEVIR Parameter

On systems containing very large amounts of nonpaged pool memory, MEMORY CHANNEL may be unable to complete initialization. If this happens, the console displays the following message repeatedly:

Hub timeout - reinitializing adapter

To fix this problem, examine the value of the SYSGEN parameter NPAGEVIR. If its value is greater than 1 gigabyte, consider lowering it to about half of that. Thereafter, a reboot of your system should allow the MEMORY CHANNEL to complete initialization.

B.1.6 Configurations

Figure B–4 shows a basic MEMORY CHANNEL cluster that uses the SCSI interconnect for storage. This configuration provides two advantages: high performance on the MEMORY CHANNEL interconnect and low cost on the SCSI interconnect.

Figure B–4 MEMORY CHANNEL- and SCSI-Based Cluster

In a configuration like the one shown in Figure B–4, the MEMORY CHANNEL interconnect handles internode communication while the SCSI bus handles storage communication.

You can integrate MEMORY CHANNEL with your current systems. Figure B–5 shows an example of how to add MEMORY CHANNEL to a mixed-architecture CI- and SCSI-based cluster. In this example, the BI- and XMI-based VAX systems are joined in the same CI cluster with the PCI-based Alpha MEMORY CHANNEL systems.
Because the MEMORY CHANNEL interconnect is not used for storage and booting, you must provide access to a boot device through one of the other interconnects. To use Figure B–5 as an example, one of the CI-based disks would be a good choice for a boot device because all nodes have direct access to it over the CI.

MEMORY CHANNEL can also be integrated into an existing DSSI cluster, as shown in Figure B–6.
As Figure B–6 shows, the three MEMORY CHANNEL systems and the VAX system have access to the storage that is directly connected to the DSSI interconnect as well as to the SCSI storage attached to the HSD controller. In this configuration, MEMORY CHANNEL handles the Alpha internode traffic, while the DSSI handles the storage traffic.

B.1.6.1 Configuration Support

MEMORY CHANNEL supports the platforms and configurations shown in Table B–1.

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
<td>MEMORY CHANNEL supports the following configurations:</td>
</tr>
<tr>
<td></td>
<td>• Up to eight nodes per MEMORY CHANNEL hub.</td>
</tr>
<tr>
<td></td>
<td>• For two-hub configurations, up to two PCI adapters per node; each adapter must be connected to a different hub.</td>
</tr>
<tr>
<td></td>
<td>• For two-node configurations, no hub is required.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

**Note**

You can configure a computer in an OpenVMS Cluster system with both a MEMORY CHANNEL Version 1.5 hub and a MEMORY CHANNEL Version 2.0 hub. However, the version number of the adapter and the cables must match the hub's version number for MEMORY CHANNEL to function properly.

In other words, you must use MEMORY CHANNEL Version 1.5 adapters with the MEMORY CHANNEL Version 1.5 hub and MEMORY CHANNEL Version 1.5 cables. Similarly, you must use MEMORY CHANNEL Version 2.0 adapters with the MEMORY CHANNEL Version 2.0 hub and MEMORY CHANNEL Version 2.0 cables.

B.2 Technical Overview

This section describes in more technical detail how MEMORY CHANNEL works.

B.2.1 Comparison With Traditional Networks and SMP

You can think of MEMORY CHANNEL as a form of “stretched SMP bus” that supports enough physical distance to interconnect up to eight systems. However, MEMORY CHANNEL differs from an SMP environment where multiple CPUs can directly access the same physical memory. MEMORY CHANNEL requires each node to maintain its own physical memory, even though the nodes share MEMORY CHANNEL global address space.

MEMORY CHANNEL fills a price/performance gap between the high performance of SMP systems and traditional packet-based networks. Table B–2 shows a comparison among the characteristics of SMP, MEMORY CHANNEL, and standard networks.

B.2.2 MEMORY CHANNEL in the OpenVMS Cluster Architecture

As Figure B–7 shows, MEMORY CHANNEL functionality has been implemented in the OpenVMS Cluster architecture just below the System Communication Services layer. This design ensures that no changes are required to existing applications because higher layers of OpenVMS Cluster software are unchanged.

Figure B–7 OpenVMS Cluster Architecture and MEMORY CHANNEL

MEMORY CHANNEL software consists of two new drivers:

</thead>
<tbody>
<tr>
<td>PMDRIVER</td>
<td>Emulates a cluster port driver.</td>
</tr>
<tr>
<td>MCDRIVER</td>
<td>Provides MEMORY CHANNEL services and an interface to MEMORY CHANNEL hardware.</td>
</tr>
</tbody>
</table>

B.2.3 MEMORY CHANNEL Addressing

In a MEMORY CHANNEL configuration, a section of system physical address space is shared among all nodes. When a system writes data to this address space, the MEMORY CHANNEL hardware also performs a global write so that this data is stored in the memories of other systems. In other words, when a node’s CPU writes data to the PCI address space occupied by the MEMORY CHANNEL adapter, the data is sent across the MEMORY CHANNEL interconnect to the other nodes. The other nodes’ PCI adapters map this data into their own memory. This infrastructure enables a write to an I/O address on one system to get mapped to a physical address on the other system. The next two figures explain this in more detail.
Figure B–8 shows how MEMORY CHANNEL global address space is addressed in physical memory.

Figure B–8 Physical Memory and I/O Address Space

Every system in a MEMORY CHANNEL cluster allocates this address space for MEMORY CHANNEL data and communication. By using this address space, a CPU can perform global writes to the memories of other nodes.

To explain global writes more fully, Figure B–9 shows the internal bus architecture of two nodes, node A and node B.
In the example shown in Figure B–9, node A is performing a global write to node B’s memory, in the following sequence:

1. Node A’s CPU performs a write to MEMORY CHANNEL address space, which is part of PCI address space. The write makes its way through the PCI bus to the PCI/MEMORY CHANNEL adapter and out on the MEMORY CHANNEL interconnect.

2. Node B’s PCI adapter receives the data, which is picked up by its PCI bus and DMA-mapped to memory.

If all nodes in the cluster agree to address MEMORY CHANNEL global address space in the same way, they can virtually “share” the same address space and the same data. This is why MEMORY CHANNEL address space is depicted as a common, central address space in Figure B–9.

MEMORY CHANNEL global address space is divided into pages of 8 KB (8,192 bytes). These are called MC pages. These 8 KB pages can be mapped similarly among systems.

The “shared” aspect of MEMORY CHANNEL global address space is set up using the page control table, or PCT, in the PCI adapter. The PCT has attributes that can be set for each MC page. Table B–3 explains these attributes.
Table B–3 MEMORY CHANNEL Page Attributes

<table>

</tr>
<tr>
<td>Suppress transmit/receive after error</td>
<td>Specifies that if an error occurs on this page, transmit and receive operations are not allowed until the error condition is cleared.</td>
</tr>
<tr>
<td>ACK</td>
<td>A write to a page causes each receiving system's adapter to respond with an ACK (acknowledge), ensuring that a write (or other operation) has occurred on remote nodes without interrupting their hosts. This is used for error checking and error recovery.</td>
</tr>
</tbody>
</table>

B.2.4 MEMORY CHANNEL Implementation

MEMORY CHANNEL software comes bundled with the OpenVMS Cluster software. After setting up the hardware, you configure the MEMORY CHANNEL software by responding to prompts in the CLUSTER_CONFIG.COM procedure. A prompt asks whether you want to enable MEMORY CHANNEL for node-to-node communications for the local computer. By responding “Yes”, MC_SERVICES_P2, the system parameter that controls whether MEMORY CHANNEL is in effect, is set to 1. This setting causes the driver, PMDRIVER, to be loaded and the default values for the other MEMORY CHANNEL system parameters to take effect.

For a description of all the MEMORY CHANNEL system parameters, refer to the OpenVMS Cluster Systems manual.

For more detailed information about setting up the MEMORY CHANNEL hub, link cables, and PCI adapters, see the MEMORY CHANNEL User’s Guide, order number EK-PCIMC-UG.A01.
This appendix describes the CI-to-PCI adapter (CIPCA) which was introduced in OpenVMS Alpha Version 6.2–1H2 and is supported on all subsequent versions, except OpenVMS Version 7.0. The CIPCA adapter supports specific Alpha servers and OpenVMS Cluster configurations.

This appendix contains the following sections:
• CIPCA overview (Section C.1)
• Technical specifications (Section C.2)
• Configuration support and restrictions (Section C.3)
• Installation requirements (Section C.4)
• DECEvent for Analyzing CIPCA Errors (Section C.5)
• Performance recommendations (Section C.6)

C.1 CIPCA Overview

The CIPCA adapter, developed in partnership with CMD Technologies, enables Alpha servers with PCI buses or with a PCI bus and an EISA bus to connect to the CI. The CIPCA adapter provides the following features and benefits:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Benefit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower entry cost and more configuration choices</td>
<td>If you require midrange compute power for your business needs, CIPCA enables you to integrate midrange Alpha servers into your existing CI cluster.</td>
</tr>
<tr>
<td>High-end Alpha speed and power</td>
<td>If you require maximum compute power, you can use the CIPCA with both the AlphaServer 8200 systems and AlphaServer 8400 systems that have PCI and EISA I/O subsystems.</td>
</tr>
<tr>
<td>Cost-effective Alpha migration path</td>
<td>If you want to add Alpha servers to an existing CI VAXcluster, CIPCA provides a cost-effective way to start migrating to a mixed-architecture cluster in the price/performance range that you need.</td>
</tr>
</tbody>
</table>
CIPCA Overview

Advantages of the CI

The CIPCA connects to the CI, which offers the following advantages:

- High speed to accommodate larger processors and I/O-intensive applications.
- Efficient, direct access to large amounts of storage.
- Minimal CPU overhead for communication. CI adapters are intelligent interfaces that perform much of the communication work in OpenVMS Cluster systems.
- High availability through redundant, independent data paths, because each CI adapter is connected with two pairs of CI cables.
- Multiple access paths to disks and tapes.

Figure C–1 shows an example of a mixed-architecture CI OpenVMS Cluster that has two servers: an Alpha and a VAX.

Figure C–1  CIPCA in a Mixed-Architecture OpenVMS Cluster

As Figure C–1 shows, you can use the CIPCA adapter to connect an Alpha server to a CI OpenVMS Cluster that contains a VAX server with a CIXCD (or CIBCA-B) adapter. This enables you to smoothly integrate an Alpha server into a cluster that previously comprised only high-end VAX systems.
Figure C–2 shows another example of a configuration that uses the CIPCA to connect systems with the CI. In this example, each Alpha has two CIPCA adapters that allow connectivity to multiple CI star couplers and HSJ storage controllers for I/O load balancing or for OpenVMS shadow-set member isolation. Also, the Alpha systems are connected to a high-speed FDDI interconnect that provides additional connectivity for PC clients and OpenVMS satellites.

**Figure C–2 CIPCA in an Alpha OpenVMS Cluster**

Figure C–1 and Figure C–2 show that the CIPCA makes the performance, availability, and large storage access of the CI available to a wide variety of users. The CI has a high maximum throughput. Both the PCI-based CIPCA and the XMI based CIXCD are highly intelligent microprocessor-controlled adapters that consume minimal CPU overhead.

Because the effective throughput of the CI bus is high, the CI interconnect is not likely to be a bottleneck. In large configurations like the one shown in Figure C–2, multiple adapters and CI connections provide excellent availability and throughput.

Although not shown in Figure C–1 and Figure C–2, you can increase availability by placing disks on a SCSI interconnect between a pair of HSJ controllers and connecting each HSJ to the CI.
CIPCA-BA was introduced second. It requires two PCI slot and is intended for newer systems with a limited number of EISA slots.

The CIPCA driver is named the SYS$PCAdriver. It is included in the OpenVMS operating system software.

Table C–1 shows the performance of the CIPCA in relation to the CIXCD adapter.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

For information about installing and operating the CIPCA, refer to the hardware manual that came with your CIPCA adapter: CIPCA PCI-CI Adapter User’s Guide.

C.3 Configuration Support and Restrictions

The CIPCA adapter is supported by AlphaServers with PCI buses, by CI-connected VAX host systems, by storage controllers, and by the CI star coupler expander.

C.3.1 AlphaServer Support

Table C–2 describes CIPCA support on AlphaServer systems with PCI buses, including the maximum number of CIPCA supported on each system.

<table>
<thead>
<tr>
<th>System</th>
<th>Maximum CIPCA</th>
<th>Comments</th>

</tr>
<tr>
<td>AlphaServer 2000, 2100</td>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>

C.3.2 CI-Connected Host System Compatibility

For CI-connected host systems, CIPCA is supported by any OpenVMS VAX host using CIXCD or CIBCA-B as well as by any OpenVMS Alpha server host using CIPCA or CIXCD. This means that an Alpha server using the CIPCA adapter can coexist on a CI bus with VAX systems using CIXCD and CIBCA-B CI adapters.

The maximum number of systems supported in an OpenVMS Cluster system, 96, is not affected by the use of one or more CIPCAs, although the maximum number of CI nodes is limited to 16 (see Section C.3.4).

C.3.3 Storage Controller Support

The CIPCA adapter can coexist on a CI bus with all variants of the HSC/HSJ controllers except the HSC50. Certain controllers require specific firmware and hardware, as shown in Table C–3.

Table C–3 Controller Requirements for Supporting CIPCA

<table>
<thead>
<tr>
<th>Controller</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>HSJ 30, HSJ 40</td>
<td>HSOF Version 2.5 (or higher) firmware</td>
</tr>
<tr>
<td>HSC40, HSC70</td>
<td>Revision F (or higher) L109 module</td>
</tr>
<tr>
<td>HSJ 80</td>
<td>ACS V8.5J (or higher) firmware</td>
</tr>
</tbody>
</table>

C.3.4 Star Coupler Expander Support

A CI star coupler expander (CISCE) can be added to any star coupler to increase its connection capacity to 32 ports. The maximum number of CPUs that can be connected to a star coupler is 16, regardless of the number of ports.

C.3.5 Configuration Restrictions

Note the following configuration restrictions:

CIPCA-AA with EISA-Slot Link Module Rev. A01

For the CIPCA-AA adapter with the EISA-slot link module Rev. A01, use the DIP switch settings described here to prevent arbitration timeout errors. Under heavy CI loads, arbitration timeout errors can cause CI path errors and CI virtual circuit closures.
CI-to-PCI Adapter (CIPCA) Support

C.3 Configuration Support and Restrictions

The DIP switch settings on the CIPCA-AA link module are used to specify cluster size and the node address. Follow these instructions when setting the DIP switches for link module Rev. A01 only:

- If the cluster size is set to 16, do not set a CI adapter to node address 15 on that star coupler.
- If the cluster size is set to 32, do not set a CI adapter to node address 31 on that star coupler. Also, do not set any CIPCA to node address 0 or do not set any CI adapter to node address 16.

These restrictions do not apply to the EISA slot link module Rev. B01 and higher or to the PCI-slot link module of the CIPCA-BA.

HSJ50 Firmware Requirement for Use of 4K CI Packets

Do not attempt to enable the use of 4K CI packets by the HSJ50 controller unless the HSJ50 firmware is Version 5.0J–3 or higher. If the HSJ50 firmware version is less than Version 5.0J–3 and 4K CI packets are enabled, data can become corrupted. If your HSJ50 firmware does not meet this requirement, contact your Compaq support representative.

C.4 Installation Requirements

When installing CIPCA adapters in your cluster, observe the following version-specific requirements.

C.4.1 Managing Bus Addressable Pool (BAP) Size

The CIPCA, CIXCD, and KFMSB adapters use bus-addressable pool (BAP). Starting with OpenVMS Version 7.1, AUTOGEN controls the allocation of BAP. After installing or upgrading the operating system, you must run AUTOGEN with the FEEDBACK qualifier. When you run AUTOGEN in this way, the following four system parameters are set:

- NPAG_BAP_MIN
- NPAG_BAP_MAX
- NPAG_BAP_MIN_PA
- NPAG_BAP_MAX_PA

The BAP allocation amount depends on the adapter type, the number of adapters, and the version of the operating system. The size of physical memory determines whether the BAP remains separate or is merged with normal, nonpaged dynamic memory (NPAGEDYN), as shown in Table C–4.

<table>
<thead>
<tr>
<th>Adapter</th>
<th>Version 7.1</th>
<th>Version 7.2</th>
<th>Separate BAP or Merged</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIPCA</td>
<td>4 MB</td>
<td>2 MB</td>
<td>Separate if physical memory &gt;1 GB; otherwise merged</td>
</tr>
<tr>
<td>CIXCD</td>
<td>4 MB</td>
<td>2 MB</td>
<td>Separate if physical memory &gt;4 GB; otherwise merged</td>
</tr>
<tr>
<td>KFMSB</td>
<td>8 MB</td>
<td>4 MB</td>
<td>Separate if physical memory &gt;4 GB; otherwise merged</td>
</tr>
</tbody>
</table>

Table C–4 BAP Allocation by Adapter Type and OpenVMS Version
For systems whose BAP is merged with nonpaged pool, the initial amount and maximum amount of nonpaged pool (as displayed by the DCL command SHOW MEMORY/POOL/FULL) do not match the value of the SYSGEN parameters NPAGEDYN and NPAGEVIR. Instead, the value of SYSGEN parameter NPAG_BAP_MIN is added to NPAGEDYN to determine the initial size, and the value of NPAG_BAP_MAX is added to NPAGEVIR to determine the maximum size.

Your OpenVMS system may not require as much merged pool as the sum of these SYSGEN parameters. After your system has been running a few days, use AUTOGEN with the FEEDBACK qualifier to fine-tune the amount of memory allocated for the merged, nonpaged pool.

**C.4.2 AUTOCONFIGURE Restriction for OpenVMS Version 6.2-1H2 and OpenVMS Version 6.2-1H3**

When you perform a normal installation boot, AUTOCONFIGURE runs automatically. AUTOCONFIGURE is run from SYS$STARTUP:VMS$DEVICE_STARTUP.COM (called from SYS$SYSTEM:STARTUP.COM), unless disabled by SYSMAN. If you are running OpenVMS Version 6.2-1H2 or OpenVMS Version 6.2-1H3 and you have customized your booting sequence, make sure that AUTOCONFIGURE runs or that you explicitly configure all CIPCA devices before SYSTARTUP_VMS.COM exits.

**C.5 DECevent for Analyzing CIPCA Errors**

To analyze error log files for CIPCA errors, use DECevent. The DCL command ANALYZE/ERROR_LOG has not been updated to support CIPCA and other new devices; using that command will result in improperly formatted error log entries.

Install the DECevent kit supplied on the OpenVMS Alpha CD-ROM. Then use the following DCL commands to invoke DECevent to analyze dump files:

- **DIAGNOSE** — Analyzes the current system error log file
- **DIAGNOSE filename** — Analyzes the error log file named filename.sys

For more information about using DECevent, use the DCL HELP DIAGNOSE command.

**C.6 Performance Recommendations**

To enhance performance, follow the recommendations that pertain to your configuration.

**C.6.1 Synchronous Arbitration**

CIPCA uses a new, more optimal CI arbitration algorithm called synchronous arbitration instead of the older asynchronous arbitration algorithm. The two algorithms are completely compatible. Under CI saturation conditions, both the old and new algorithms are equivalent and provide equitable round-robin access to all nodes. However, with less traffic, the new algorithm provides the following benefits:

- Reduced packet transmission latency due to reduced average CI arbitration time.
- Increased node-to-node throughput.
- Complete elimination of CI collisions that waste bandwidth and increase latency in configurations containing only synchronous arbitration nodes.
CI-to-PCI Adapter (CIPCA) Support

C.6 Performance Recommendations

- Reduced CI collision rate in configurations with mixed synchronous and asynchronous arbitration CI nodes. The reduction is roughly proportional to the fraction of CI packets being sent by the synchronous arbitration CI nodes.

Support for synchronous arbitration is latent in the HSJ controller family. In configurations containing both CIPCA s and HSJ controllers, enabling the HSJs to use synchronous arbitration is recommended.

The HSJ CLI command to do this is:

```
CLI> SET THIS CI_ARB = SYNC
```

This command will take effect upon the next reboot of the HSJ.

C.6.2 Maximizing CIPCA Performance With an HSJ50 and an HSJ80

To maximize the performance of the CIPCA adapter with an HSJ 50 or HSJ 80 controller, it is advisable to enable the use of 4K CI packets by the HSJ 50 or HSJ 80. For the HSJ 50, the firmware revision level must be at Version 5.0J -3 or higher. For the HSJ 80, the firmware revision level must be at ACS V8.5J or higher.

--- Caution ---

Do not attempt to use 4K CI packets if your HSJ 50 firmware revision level is not Version 5.0J -3 or higher, because data can become corrupted.

---

To enable the use of 4K CI packets, specify the following command at the HSJ 50 or HSJ 80 console prompt:

```
CLI> SET THIS_CONTROLLER CI_4K_PACKET_CAPABILITY
```

This command takes effect when the HSJ 50 is rebooted.
This appendix describes multiple-site OpenVMS Cluster configurations in which multiple nodes are located at sites separated by relatively long distances, from approximately 25 to 125 miles, depending on the technology used. This configuration was introduced in OpenVMS Version 6.2. General configuration guidelines are provided and the three technologies for connecting multiple sites are discussed. The benefits of multiple site clusters are cited and pointers to additional documentation are provided.

The information in this appendix supersedes the Multiple-Site VMScluster Systems addendum manual.

D.1 What is a Multiple-Site OpenVMS Cluster System?

A multiple-site OpenVMS Cluster system is an OpenVMS Cluster system in which the member nodes are located in geographically separate sites. Depending on the technology used, the distances can be as great as 150 miles.

When an organization has geographically dispersed sites, a multiple-site OpenVMS Cluster system allows the organization to realize the benefits of OpenVMS Cluster systems (for example, sharing data among sites while managing data center operations at a single, centralized location).

Figure D–1 illustrates the concept of a multiple-site OpenVMS Cluster system for a company with a manufacturing site located in Washington, D.C., and corporate headquarters in Philadelphia. This configuration spans a geographical distance of approximately 130 miles (210 km).
D.1 What is a Multiple-Site OpenVMS Cluster System?

D.1.1 ATM, DS3, and FDDI Intersite Links

The following link technologies between sites are approved for OpenVMS VAX and OpenVMS Alpha systems:

- Asynchronous transfer mode (ATM)
- DS3
- FDDI

High-performance local area network (LAN) technology combined with the ATM, DS3, and FDDI interconnects allows you to utilize wide area network (WAN) communication services in your OpenVMS Cluster configuration. OpenVMS Cluster systems configured with the GIGAswitch crossbar switch and ATM, DS3, or FDDI interconnects approve the use of nodes located miles apart. (The actual distance between any two sites is determined by the physical intersite cable-route distance, and not the straight-line distance between the sites.) Section D.3 describes OpenVMS Cluster systems and the WAN communications services in more detail.

______________________________  Note  ______________________________

To gain the benefits of disaster tolerance across a multiple-site OpenVMS Cluster, use Disaster Tolerant Cluster Services for OpenVMS, a system management and software package from Compaq.

Consult your Compaq Services representative for more information.

D.1.2 Benefits of Multiple-Site OpenVMS Cluster Systems

Some of the benefits you can realize with a multiple-site OpenVMS Cluster system include the following:
### D.1 What is a Multiple-Site OpenVMS Cluster System?

<table>
<thead>
<tr>
<th>Benefit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote satellites and nodes</td>
<td>A few systems can be remotely located at a secondary site and can benefit from centralized system management and other resources at the primary site, as shown in Figure D–2. For example, a main office data center could be linked to a warehouse or a small manufacturing site that could have a few local nodes with directly attached site-specific devices. Alternatively, some engineering workstations could be installed in an office park across the city from the primary business site.</td>
</tr>
<tr>
<td>Data center management consolidation</td>
<td>A single management team can manage nodes located in data centers at multiple sites.</td>
</tr>
<tr>
<td>Physical resource sharing</td>
<td>Multiple sites can readily share devices such as high-capacity computers, tape libraries, disk archives, or phototypesetters.</td>
</tr>
<tr>
<td>Remote archiving</td>
<td>Backups can be made to archival media at any site in the cluster. A common example would be to use disk or tape at a single site to back up the data for all sites in the multiple-site OpenVMS Cluster. Backups of data from remote sites can be made transparently (that is, without any intervention required at the remote site).</td>
</tr>
<tr>
<td>Increased availability</td>
<td>In general, a multiple-site OpenVMS Cluster provides all of the availability advantages of a LAN OpenVMS Cluster. Additionally, by connecting multiple, geographically separate sites, multiple-site OpenVMS Cluster configurations can increase the availability of a system or elements of a system in a variety of ways:</td>
</tr>
<tr>
<td>• Logical volume/data availability</td>
<td>Volume shadowing or redundant arrays of independent disks (RAID) can be used to create logical volumes with members at both sites. If one of the sites becomes unavailable, data can remain available at the other site.</td>
</tr>
<tr>
<td>• Site failover</td>
<td>By adjusting the VOTES system parameter, you can select a preferred site to continue automatically if the other site fails or if communications with the other site are lost.</td>
</tr>
<tr>
<td>• Disaster tolerance</td>
<td>When combined with the software, services, and management procedures provided by the Disaster Tolerant Cluster Services for OpenVMS, you can achieve a high level of disaster tolerance. Consult your Compaq Services representative for further information.</td>
</tr>
</tbody>
</table>
Figure D–2 shows an OpenVMS Cluster system with satellites accessible from a remote site.

**D.1 What is a Multiple-Site OpenVMS Cluster System?**

The same configuration rules that apply to OpenVMS Cluster systems on a LAN also apply to a multiple-site OpenVMS Cluster configuration that includes ATM, DS3, or FDDI intersite interconnect. General LAN configuration rules are stated in the following documentation:

- OpenVMS Cluster Software Software Product Description (SPD 29.78.xx)
- Chapter 8 of this manual

Some configuration guidelines are unique to multiple-site OpenVMS Clusters; these guidelines are described in Section D.3.4.

**D.2 Using FDDI to Configure Multiple-Site OpenVMS Cluster Systems**

Since VMS Version 5.4–3, FDDI has been the most common method to connect two distant OpenVMS Cluster sites. Using high-speed FDDI fiber-optic cables, you can connect sites with an intersite cable-route distance of up to 25 miles (40 km), the cable route distance between sites.

You can connect sites using these FDDI methods:

- To obtain maximum performance, use a full-duplex FDDI link at 100 Mb/s both ways between GIGA switch/FDDI bridges at each site for maximum intersite bandwidth.
- To obtain maximum availability, use a dual FDDI ring at 100 Mb/s between dual attachment stations (DAS) ports of wiring concentrators or GIGA switch/FDDI bridges for maximum link availability.
D.2 Using FDDI to Configure Multiple-Site OpenVMS Cluster Systems

- For maximum performance and availability, use two disjoint FDDI LANs, each with dedicated host adapters and full-duplex FDDI intersite links connected to GIGAswitch/FDDI bridges at each site.

Refer to the GIGAswitch/ FDDI ATM Linecard Reference Manual for configuration information. Additional OpenVMS Cluster configuration guidelines and system management information can be found in this manual and in OpenVMS Cluster Systems. See the New Features and Documentation Overview Manual for information about ordering the current version of these manuals.

The inherent flexibility of OpenVMS Cluster systems and improved OpenVMS Cluster LAN protocols also allow you to connect multiple OpenVMS Cluster sites using the ATM or DS3 or both communications services.

D.3 Using WAN Services to Configure Multiple-Site OpenVMS Cluster Systems

This section provides an overview of the ATM and DS3 wide area network (WAN) services, describes how you can bridge an FDDI interconnect to the ATM or DS3 or both communications services, and provides guidelines for using these services to configure multiple-site OpenVMS Cluster systems.

The ATM and DS3 services provide long-distance, point-to-point communications that you can configure into your OpenVMS Cluster system to gain WAN connectivity. The ATM and DS3 services are available from most common telephone service carriers and other sources.

Note

DS3 is not available in Europe and some other locations. Also, ATM is a new and evolving standard, and ATM services might not be available in all localities.

ATM and DS3 services are approved for use with the following OpenVMS versions:

<table>
<thead>
<tr>
<th>Service</th>
<th>Approved Versions of OpenVMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATM</td>
<td>OpenVMS Version 6.2 or later</td>
</tr>
<tr>
<td>DS3</td>
<td>OpenVMS Version 6.1 or later</td>
</tr>
</tbody>
</table>

The following sections describe the ATM and DS3 communication services and how to configure these services into multiple-site OpenVMS Cluster systems.

D.3.1 The ATM Communications Service

The ATM communications service that uses the SONET physical layer (ATM/SONET) provides full-duplex communications (that is, the bit rate is available simultaneously in both directions as shown in Figure D–3). ATM/SONET is compatible with multiple standard bit rates. The SONET OC-3 service at 155 Mb/s full-duplex rate is the best match to FDDI’s 100 Mb/s bit rate. ATM/SONET OC-3 is a standard service available in most parts of the world. In Europe, ATM/SONET is a high-performance alternative to the older E3 standard.
To transmit data, ATM frames (packets) are broken into cells for transmission by the ATM service. Each cell has 53 bytes, of which 5 bytes are reserved for header information and 48 bytes are available for data. At the destination of the transmission, the cells are reassembled into ATM frames. The use of cells permits ATM suppliers to multiplex and demultiplex multiple data streams efficiently at differing bit rates. This conversion of frames into cells and back is transparent to higher layers.

D.3.2 The DS3 Communications Service (T3 Communications Service)

The DS3 communications service provides full-duplex communications as shown in Figure D–4. DS3 (also known as T3) provides the T3 standard bit rate of 45 Mb/s. T3 is the standard service available in North America and many other parts of the world.

D.3.3 FDDI-to-WAN Bridges

You can use FDDI-to-WAN (for example, FDDI-to-ATM or FDDI-to-DS3 or both) bridges to configure an OpenVMS Cluster with nodes in geographically separate sites, such as the one shown in Figure D–5. In this figure, the OpenVMS Cluster nodes at each site communicate as though the two sites are connected by FDDI. The FDDI-to-WAN bridges make the existence of ATM and DS3 transparent to the OpenVMS Cluster software.
In Figure D–5, the FDDI-to-DS3 bridges and DS3 operate as follows:

1. The local FDDI-to-DS3 bridge receives FDDI packets addressed to nodes at the other site.
2. The bridge converts the FDDI packets into DS3 packets and sends the packets to the other site via the DS3 link.
3. The receiving FDDI-to-DS3 bridge converts the DS3 packets into FDDI packets and transmits them on an FDDI ring at that site.

Compaq recommends using the GIGAswitch/FDDI system to construct FDDI-to-WAN bridges. The GIGAswitch/FDDI, combined with the DEFGT WAN T3/SONET option card, was used during qualification testing of the ATM and DS3 communications services in multiple-site OpenVMS Cluster systems.

D.3.4 Guidelines for Configuring ATM and DS3 in an OpenVMS Cluster System

When configuring a multiple-site OpenVMS Cluster, you must ensure that the intersite link's delay, bandwidth, availability, and bit error rate characteristics meet application needs. This section describes the requirements and provides recommendations for meeting those requirements.

D.3.4.1 Requirements

To be a configuration approved by Compaq, a multiple-site OpenVMS Cluster must comply with the following rules:

Maximum intersite link route distance

The total intersite link cable route distance between members of a multiple-site OpenVMS Cluster cannot exceed 150 miles (242 km). You can obtain exact distance measurements from your ATM or DS3 supplier. This distance restriction can be exceeded when using Disaster Tolerant Cluster Services for OpenVMS, a system management and software package for configuring and managing OpenVMS disaster tolerant clusters.
D.3 Using WAN Services to Configure Multiple-Site OpenVMS Cluster Systems

Maximum intersite link utilization

Average intersite link utilization in either direction must be less than 80% of the link’s bandwidth in that direction for any 10-second interval. Exceeding this utilization is likely to result in intolerable queuing delays or packet loss.

Intersite link specifications

The intersite link must meet the OpenVMS Cluster requirements specified in Table D–3.

OpenVMS Cluster LAN configuration rules

Apply the configuration rules for OpenVMS Cluster systems on a LAN to a configuration. Documents describing configuration rules are referenced in Section D.1.3.

D.3.4.2 Recommendations

When configuring the DS3 interconnect, apply the configuration guidelines for OpenVMS Cluster systems interconnected by LAN that are stated in the OpenVMS Cluster Software SPD (SPD 29.78.nn) and in this manual. OpenVMS Cluster members at each site can include any mix of satellites, systems, and other interconnects, such as Cl and DSSI.

This section provides additional recommendations for configuring a multiple-site OpenVMS Cluster system.

DS3 link capacity/protocols

The GIGAswitch with the WAN T3/SONET option card provides a full-duplex, 155 Mb/s ATM/SONET link. The entire bandwidth of the link is dedicated to the WAN option card. However, the GIGAswitch/FDDI’s internal design is based on full-duplex extensions to FDDI. Thus, the GIGAswitch/FDDI’s design limits the ATM/SONET link’s capacity to 100 Mb/s in each direction.

The GIGAswitch with the WAN T3/SONET option card provides several protocol options that can be used over a DS3 link. Use the DS3 link in clear channel mode, which dedicates its entire bandwidth to the WAN option card. The DS3 link capacity varies with the protocol option selected. Protocol options are described in Table D–1.

<table>
<thead>
<tr>
<th>Protocol Option</th>
<th>Link Capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATM¹ AAL–5² mode with PLCP³ disabled.</td>
<td>39 Mb/s</td>
</tr>
<tr>
<td>ATM AAL–5 mode with PLCP enabled.</td>
<td>33 Mb/s</td>
</tr>
<tr>
<td>HDLC⁴ mode (not currently available).</td>
<td>43 Mb/s</td>
</tr>
</tbody>
</table>

¹Asynchronous transfer mode
²ATM Adaptation Layer
³Physical Layer Convergence Protocol
⁴High-Speed Datalink Control

For maximum link capacity, Compaq recommends configuring the WAN T3/SONET option card to use ATM AAL–5 mode with PLCP disabled.
Intersite bandwidth

The intersite bandwidth can limit application locking and I/O performance (including volume shadowing or RAID set copy times) and the performance of the lock manager.

To promote reasonable response time, Compaq recommends that average traffic in either direction over an intersite link not exceed 60% of the link's bandwidth in that direction for any 10-second interval. Otherwise, queuing delays within the FDDI-to-WAN bridges can adversely affect application performance.

Remember to account for both OpenVMS Cluster communications (such as locking and I/O) and network communications (such as TCP/IP, LAT, and DECnet) when calculating link utilization.

Intersite delay

An intersite link introduces a one-way delay of up to 1 ms per 100 miles of intersite cable route distance plus the delays through the FDDI-to-WAN bridges at each end. Compaq recommends that you consider the effects of intersite delays on application response time and throughput.

For example, intersite link one-way path delays have the following components:

- Cable route one-way delays of 1 ms/100 miles (0.01 ms/mile) for both ATM and DS3.
- FDDI-to-WAN bridge delays (approximately 0.5 ms per bridge, and two bridges per one-way trip)

Calculate the delays for a round trip as follows:

\[ \text{WAN round-trip delay} = 2 \times (N \text{ miles} \times 0.01 \text{ ms per mile} + 2 \times 0.5 \text{ ms per FDDI-WAN bridge}) \]

An I/O write operation that is MSCP served requires a minimum of two round-trip packet exchanges:

\[ \text{WAN I/O write delay} = 2 \times \text{WAN round-trip delay} \]

Thus, an I/O write over a 100-mile WAN link takes at least 8 ms longer than the same I/O write over a short, local FDDI.

Similarly, a lock operation typically requires a round-trip exchange of packets:

\[ \text{WAN lock operation delay} = \text{WAN round-trip delay} \]

An I/O operation with \( N \) locks to synchronize it incurs the following delay due to WAN:

\[ \text{WAN locked I/O operation delay} = (N \times \text{WAN lock operation delay}) + \text{WAN I/O delay} \]

Bit error ratio

The bit error ratio (BER) parameter is an important measure of the frequency that bit errors are likely to occur on the intersite link. You should consider the effects of bit errors on application throughput and responsiveness when configuring a multiple-site OpenVMS Cluster. Intersite link bit errors can result in packets being lost and retransmitted with consequent delays in application I/O response time (see Section D.3.6). You can expect application delays ranging from a few hundred milliseconds to a few seconds each time a bit error causes a packet to be lost.
Multiple-Site OpenVMS Clusters
D.3 Using WAN Services to Configure Multiple-Site OpenVMS Cluster Systems

Intersite link availability
Interruptions of intersite link service can result in the resources at one or more sites becoming unavailable until connectivity is restored (see Section D.3.5).

System disks
Sites with nodes contributing quorum votes should have a local system disk or disks for those nodes.

System management
A large, multiple-site OpenVMS Cluster requires a system management staff trained to support an environment that consists of a large number of diverse systems that are used by many people performing varied tasks.

Microwave DS3 links
You can provide portions of a DS3 link with microwave radio equipment. The specifications in Section D.3.6 apply to any DS3 link. The BER and availability of microwave radio portions of a DS3 link are affected by local weather and the length of the microwave portion of the link. Consider working with a microwave consultant who is familiar with your local environment if you plan to use microwaves as portions of a DS3 link.

D.3.5 Availability Considerations
If the FDDI-to-WAN bridges and the link that connects multiple sites become temporarily unavailable, the following events could occur:

- Intersite link failures can result in the resources at one or more sites becoming unavailable until intersite connectivity is restored.

- Intersite link bit errors (and ATM cell losses) and unavailability can affect:
  - System responsiveness
  - System throughput (or bandwidth)
  - Virtual circuit (VC) closure rate
  - OpenVMS Cluster transition and site failover time

Many communication service carriers offer availability-enhancing options, such as path diversity, protective switching, and other options that can significantly increase the intersite link’s availability.

D.3.6 Specifications
This section describes the requirements for successful communications and performance with the WAN communications services.

To assist you in communicating your requirements to a WAN service supplier, this section uses WAN specification terminology and definitions commonly used by telecommunications service providers. These requirements and goals are derived from a combination of Bellcore Communications Research specifications and a Digital analysis of error effects on OpenVMS Clusters.

Table D–2 describes terminology that will help you understand the Bellcore and OpenVMS Cluster requirements and goals used in Table D–3.

Use the Bellcore and OpenVMS Cluster requirements for ATM/SONET - OC3 and DS3 service error performance (quality) specified in Table D–3 to help you assess the impact of the service supplier’s service quality, availability, down time, and service-interruption frequency goals on the system.
To ensure that the OpenVMS Cluster system meets your application response-time requirements, you might need to establish WAN requirements that exceed the Bellcore and OpenVMS Cluster requirements and goals stated in Table D–3.

Table D–2 Bellcore and OpenVMS Cluster Requirements and Goals Terminology

<table>
<thead>
<tr>
<th>Specification</th>
<th>Requirements</th>
<th>Goals</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bellcore Communications Research</td>
<td>Bellcore specifications are the recommended “generic error performance requirements and objectives” documented in the Bellcore Technical Reference TR–TSY–000499 TSGR: Common Requirements. These specifications are adopted by WAN suppliers as their service guarantees. The FCC has also adopted them for tariffed services between common carriers. However, some suppliers will contract to provide higher service-quality guarantees at customer request. Other countries have equivalents to the Bellcore specifications and parameters.</td>
<td>These are the recommended minimum values. Bellcore calls these goals their “objectives” in the TSGR: Common Requirements document. For optimal OpenVMS Cluster operation, all parameters should meet or exceed the OpenVMS Cluster Goal values. Note that if these values are met or exceeded, then interconnect bit errors and bit error recovery delays should not significantly degrade average OpenVMS Cluster throughput. OpenVMS Cluster response time should be generally satisfactory, although there may be brief application pauses a few times per day.2</td>
</tr>
<tr>
<td>OpenVMS Cluster</td>
<td>In order for Compaq to approve a configuration, parameters must meet or exceed the values shown in the OpenVMS Cluster Requirements column in Table D–3. If these values are not met, OpenVMS Cluster performance will probably be unsatisfactory because of interconnect errors/error recovery delays, and VC closures that may produce OpenVMS Cluster state transitions or site failover or both. If these values are met or exceeded, then interconnect bit error-related recovery delays will not significantly degrade average OpenVMS Cluster throughput. OpenVMS Cluster response time should be generally satisfactory. Note that if the requirements are only being met, there may be several application pauses per hour.1</td>
<td></td>
</tr>
</tbody>
</table>

1Application pauses may occur every hour or so (similar to what is described under OpenVMS Cluster Requirements) because of packet loss caused by bit error.

2Pauses are due to a virtual circuit retransmit timeout resulting from a lost packet on one or more NISCA transport virtual circuits. Each pause might last from a few hundred milliseconds to a few seconds.
D.3 Using WAN Services to Configure Multiple-Site OpenVMS Cluster Systems

</tbody>
</table>

1 Application requirements might need to be more rigorous than those shown in the OpenVMS Cluster Requirements column.
2 Averaged over many days.
3 Does not include any burst errored seconds occurring in the measurement period.
4 The average number of channel down-time periods occurring during a year. This parameter is useful for specifying how often a channel might become unavailable.

Table Key

- **Availability**—The long-term fraction or percentage of time that a transmission channel performs as intended. Availability is frequently expressed in terms of unavailability or down time.
- **BER (bit error ratio)**—“The BER is the ratio of the number of bits in error to the total number of bits transmitted during a measurement period, excluding all burst errored seconds (defined below) in the measurement period. During a burst errored second, neither the number of bit errors nor the number of bits is counted.”
- **BES (burst errored second)**—“A burst errored second is any errored second containing at least 100 errors.”
- **Channel**—The term for a link that is used in the Bellcore TSGR: Common Requirements document for a SONET or DS3 link.
- **Down time**—The long-term average amount of time (for example, minutes) that a transmission channel is not available during a specified period of time (for example, 1 year).

...unavailability or downtime of a channel begins when the first of 10 (or more) consecutive Severely Errored Seconds (SESs) occurs, and ends when the first of 10 consecutive non-SESs occurs."

The unavailable time is counted from the first SES in the 10-SES sequence.

“The time for the end of unavailable time is counted from the first fault-free second in the [non-SES] sequence.”

- **ES (errored second)**—“An errored second is any one-second interval containing at least one error.”
- **SES (severely errored second)**—“...an SES is a second in which the BER is greater than 10⁻³.”

D.4 Managing OpenVMS Cluster Systems Across Multiple Sites

In general, you manage a multiple-site OpenVMS Cluster using the same tools and techniques that you would use for any OpenVMS Cluster interconnected by a LAN. The following sections describe some additional considerations and recommends some system management tools and techniques.
The following table lists system management considerations specific to multiple-site OpenVMS Cluster systems.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiple-site configurations present an increased probability of the following failure modes:</td>
<td>Assign votes so that one preferred site has sufficient votes to maintain quorum and to continue operation if the site-to-site communication link fails or if the other site is unavailable. Select the site with the most critical applications as the primary site. Sites with a few noncritical systems or satellites probably should not have sufficient votes to continue.</td>
</tr>
<tr>
<td>• OpenVMS Cluster quorum loss resulting from site-to-site communication link failure.</td>
<td>Consider the following options for setting user expectations:</td>
</tr>
<tr>
<td>• Site loss resulting from power failure or other breakdown can affect all systems at that site.</td>
<td>• Set management and user expectations regarding the likely effects of failures, and consider training remote users in the procedures to be followed at a remote site when the system becomes unresponsive because of quorum loss or other problems.</td>
</tr>
</tbody>
</table>

Users expect that the local resources will either continue to be available or will rapidly become available after such a failure. This might not always be the case.

D.4.1 Methods and Tools

You can use the following system management methods and tools to manage both remote and local nodes:

• There are two options for remote-site console access when you use an intersite link through a DECserver in reverse LAT mode.
  – Use the following tools to connect remote consoles:
    + SET HOST/LAT command
    + POLYCENTER Console Manager
    + OpenVMS Cluster Console System (VCS)
    + Disaster Tolerant Cluster Services for OpenVMS, a Compaq system management and software package
  – Use a modem to dial up the remote system consoles.

• An alternative to remote-site console access is to have a system manager at each site.

• To enable device and processor control commands to take effect across all nodes in an OpenVMS Cluster system, use the System Management utility (SYSMAN) that is supplied with the OpenVMS operating system.
D.4 Managing OpenVMS Cluster Systems Across Multiple Sites

D.4.2 Shadowing Data

Volume Shadowing for OpenVMS allows you to shadow data volumes across multiple sites. System disks can be members of a volume shadowing or RAID set within a site; however, use caution when configuring system disk shadow set members in multiple sites. This is because it may be necessary to boot off a remote system disk shadow set member after a failure. If your system does not support FDDI booting, it will not be possible to do this.

See the Software Product Descriptions (SPDs) for complete and up-to-date details about Volume Shadowing for OpenVMS (SPD 27.29.xx) and StorageWorks RAID for OpenVMS (SPD 46.49.xx).

D.4.3 Monitoring Performance

Monitor performance for multiple-site OpenVMS Cluster systems as follows:

- Monitor the virtual circuit (VC) packet-loss count and round-trip time values using the System Dump Analyzer (SDA). The procedures for doing this are documented in OpenVMS Cluster Systems.

- Monitor the intersite link bit error ratio (BER) and packet loss using network management tools. You can use tools such as POLYCENTER NetView or DECmdc to access the GIGASwitch and WAN T3/SONET option card's management information and to set alarm thresholds. See the GIGASwitch, WAN T3/SONET card, POLYCENTER, and DECmdc documentation, as appropriate.
