OpenVMS Connectivity Developer Guide

Contains COM for OpenVMS, OpenVMS Registry, and OpenVMS Events information

July 2000

This document contains information about COM for OpenVMS, the OpenVMS Registry, and OpenVMS Events logging. It also includes information about OpenVMS and Windows NT authentication and interoperation.

Revision/Update Information: This is an updated manual.
Software Version: COM Version 1.1-B for OpenVMS
OpenVMS Alpha Version 7.2-1
Microsoft Windows NT 4.0 SP3 or higher

Compaq Computer Corporation
Houston, Texas
1 COM for OpenVMS Release Notes

1.1 COM for OpenVMS Versions .................................................. 1–1
1.2 Upgrading from a Previous Version of COM to COM Version 1.1-B for OpenVMS ................................................................. 1–2
1.2.1 You Must Repopulate the OpenVMS Registry for COM Version 1.1-B for OpenVMS ............................................................. 1–2
1.2.2 Previously Registered Applications That Use Logical Names for the Local Server Path ...................................................... 1–2
1.2.3 Changes to the Examples .................................................... 1–3
1.3 Problems Fixed in the Current Release .................................... 1–4
1.3.1 Memory Leak in COM for OpenVMS Servers ....................... 1–4
1.3.2 DCOM$RPCSS Process Resource Exhaustion ...................... 1–4
1.3.3 Passing an Interface Pointer through IDispatch ................... 1–4
1.4 Known Problems (with Fixes) in the Current Release ................ 1–4
1.4.1 Trusted-Domain Authentication Feature Requires ECO ........... 1–4
1.4.1.1 NET3004 Messages Broadcast to Administrator on Windows NT Server System ...................................................... 1–5
1.4.1.2 Password Synchronization Errors (NET5716, NET5722, NET5723) ........................................................................ 1–5
1.4.1.3 Hostmap Problem .......................................................... 1–5
1.4.2 DCERPC-E-UNKNOWNREJECT Failure (EE128302) ............. 1–5
1.4.3 DCERPC-E-WHOAREYOUFAILED Failure (EE1282FA) ....... 1–5
1.4.4 NTARPC-E-PROTOCOL_ERROR Failure (800706C0) .......... 1–5
1.4.5 Cached IID Value Not Equal to Registry Value Failure .......... 1–5
1.4.6 IGNORE_EXTAUTH Support ............................................... 1–5
1.5 Known Problems (without Fixes) in the Current Release .......... 1–6
1.5.1 Kernel Threads and Upcalls Not Supported ......................... 1–6
1.6 Limitations and Restrictions .................................................. 1–6
1.6.1 DCOM$RPCSS Stalls on Restart ......................................... 1–6
1.6.2 MIDL Limitations and Restrictions ....................................... 1–6
1.6.2.1 MIDL -w Switch ....................................................... 1–6
1.6.2.2 MIDL Compiler Treats wchar_t Literals as char .............. 1–6
1.6.2.3 SAFEARRAY Limitation ............................................... 1–7
1.6.3 DCOM$CNFG Limitations and Restrictions ......................... 1–7
1.6.3.1 DCOM$CNFG Utility and Disabling Applications: Possible Unintended Side Effects ....................................................... 1–7
1.6.4 Other Limitations and Restrictions ................................................................. 1–8
1.6.4.1 Windows 2000 Limitations ........................................................................ 1–8
1.6.4.2 COM Version 1.0 for OpenVMS and COM Version 1.1-B for OpenVMS Not Supported in the Same Cluster ......................................................... 1–8
1.6.4.3 Remote Activation of an In-Process Server ................................................ 1–8
1.6.4.4 Threading Model Supported by COM for OpenVMS ................................. 1–8
1.6.4.5 SP4 with Enhanced NTLM Enabled is Not Supported .............................. 1–8
1.6.4.6 Specifying Activation Security in CoCreateInstanceEx ............................. 1–9
1.6.4.7 RPC Communication Failures Caused by Advanced Server ..................... 1–9
1.6.4.8 Specific Error Messages ............................................................................ 1–9
1.6.4.8.1 RPC Cannot Support Failure (800706E4) .............................................. 1–9

2 OpenVMS Registry Release Notes
2.1 Release Notes ..................................................................................................... 2–1
2.1.1 No Key Change Notifications When a Key’s Attributes are Modified ............. 2–1
2.1.2 Database Searches Limited ........................................................................... 2–1
2.1.3 Key Access Policy .......................................................................................... 2–1
2.1.4 OpenVMS Registry Maximum Data Size Restrictions .................................. 2–1
2.1.5 REG$_EXQUOTA Errors ............................................................................... 2–2
2.1.6 OpenVMS Registry Maximum Database Size Restrictions ......................... 2–2

Part I COM for OpenVMS

3 Overview of COM for OpenVMS
3.1 What is COM? ..................................................................................................... 3–1
3.1.1 Suggested Reading ....................................................................................... 3–1
3.2 Overview of COM for OpenVMS ..................................................................... 3–2
3.2.1 How COM for OpenVMS Uses the OpenVMS Registry ............................... 3–4
3.3 Using COM for OpenVMS ................................................................................ 3–4
3.3.1 Developing New Applications ..................................................................... 3–5
3.3.2 Encapsulating Existing Applications ............................................................. 3–5

4 Installing the COM for OpenVMS Kit
4.1 Contents of the COM Version 1.1-B for OpenVMS Kit .................................... 4–1
4.2 Prerequisites ..................................................................................................... 4–1
4.2.1 DECwindows Motif Required to Run COM for OpenVMS ......................... 4–2
4.3 Supported COM for OpenVMS Installations .................................................. 4–2
4.4 Installing COM for OpenVMS on an OpenVMS Standalone System ............... 4–3
4.5 Upgrading COM for OpenVMS on an OpenVMS Standalone System ............. 4–4
4.6 Installing COM for OpenVMS on an OpenVMS Cluster .................................... 4–6
4.7 Upgrading COM for OpenVMS in an OpenVMS Cluster ................................. 4–8
4.8 Understanding the COM for OpenVMS Environment ..................................... 4–10
4.8.1 COM for OpenVMS Service Control Manager (SCM) ............................... 4–11
4.8.2 OpenVMS Registry Server .......................................................................... 4–11
4.8.3 Advanced Server for OpenVMS Server ....................................................... 4–11
4.8.4 ACME Server ............................................................................................. 4–12
4.8.5 RPC Endpoint Mapper ................................................................................ 4–12
4.8.6 RPC and SSPI/NTLM Layers ...................................................................... 4–13
4.8.7 OpenVMS Events ....................................................................................... 4–13
4.9 Installing COM for OpenVMS .......................................................................... 4–13
7.3.4 Required C++ Qualifiers ........................................ 7–5
7.3.5 Required C Qualifiers ........................................... 7–5
7.4 Step 4: Link the COM Application .................................. 7–5
7.4.1 Linking the Client and the Out-of-Process Component ............ 7–6
7.4.2 Linking the In-Process Component Shareable Image ................ 7–6
7.4.2.1 Creating a Symbol Vector .................................... 7–6
7.4.3 Linking the Proxy/Stub Shareable Image .......................... 7–7
7.4.3.1 Creating a Symbol Vector .................................... 7–7
7.5 Required OpenVMS Registry Entries .................................. 7–8
7.5.1 HKEY_CLASSES_ROOT\CLSID ................................. 7–8
7.5.1.1 Component CLSIDs ........................................ 7–8
7.5.1.2 Proxy/Stub CLSIDs ......................................... 7–9
7.5.2 HKEY_CLASSES_ROOT\Interface ............................... 7–9
7.6 Converting OpenVMS and Windows Error Codes to Text ............ 7–10
NTA$VMSGetMessage .................................................. 7–11

8 Authentication

8.1 What is Authentication? ............................................. 8–1
8.2 Acquiring Windows NT Credentials Using NTA$LOGON ............ 8–1
8.2.1 NTA$LOGON Optional Qualifiers ............................... 8–3
8.2.2 Examples of Using NTA$LOGON to Acquire Windows NT Credentials ............................................. 8–4
8.3 The Authentication and Credential Management (ACM) Authority .... 8–5
8.3.1 Windows NT Authentication on OpenVMS ....................... 8–5
8.3.2 Managing the ACME_SERVER Process (ACME Server Commands) .................................................. 8–6
8.3.3 Configuring the MSV1_0 ACME Agent ........................... 8–6

9 Active Template Library

9.1 COM for OpenVMS and ATL ......................................... 9–1
9.2 Developing a COM for OpenVMS Application Using ATL .......... 9–1
9.2.1 Step 1: Create the ATL Component in Microsoft Visual Studio ... 9–2
9.2.2 Step 2: Modify Generated Files for ATL Applications on OpenVMS . 9–3
9.2.2.1 Remove_ATL_MIN_CRT .................................. 9–3
9.2.2.2 IncludeATLMAIN.CXX .................................. 9–3
9.2.2.3 Modify Registration Procedure .............................. 9–3
9.2.3 Step 3: Build an Application Using the MIDL Compiler .......... 9–4
9.2.4 Step 4: Compile the ATL COM Application ...................... 9–4
9.2.4.1 Required Header File: ATLBASE.H ........................ 9–4
9.2.4.2 Required Macro Definitions ................................. 9–4
9.2.4.3 Required Include Directories ............................... 9–4
9.2.4.4 Required C++ Qualifiers .................................. 9–5
9.2.5 Step 5: Link the ATL COM Application .......................... 9–5
9.2.5.1 Linking the Client and the Out-of-Process Component ....... 9–6
9.2.5.2 Linking the In-Process Component Shareable Image ........ 9–6
9.2.5.3 Creating a Symbol Vector .................................. 9–6
9.3 ATL Samples ....................................................... 9–6
9.3.1 Out-of-Process COM Sample (TESTATL_OUTPROC) ........... 9–6
9.3.1.1 Creating the Application on Windows NT ................... 9–7
9.3.1.2 Building, Registering, and Running the Application on OpenVMS ............................................. 9–7
Part II  OpenVMS Registry

10  Overview of OpenVMS Registry

10.1  What is the Registry? .................................................. 10–1
10.1.1  Suggested Reading .................................................. 10–1
10.2  OpenVMS Registry Concepts and Definitions .......................... 10–1
10.2.1  Keys, Subkeys, and Values ....................................... 10–2
10.2.1.1  Key and Value Volatility ..................................... 10–2
10.2.1.2  Key Write-through and Write-behind .................................. 10–3
10.2.1.3  Linking a Key to Other Keys and Values .............................. 10–3
10.2.1.4  Rules for Creating OpenVMS Registry Keys and Value Names .................. 10–3
10.2.2  Class ........................................................................ 10–4
10.2.3  Hive .......................................................................... 10–4
10.3  OpenVMS Registry Structure .......................................... 10–4
10.4  Reading and Writing to the OpenVMS Registry ...................... 10–6
10.4.1  $REGISTRY System Services ....................................... 10–6
10.4.2  REG$CP Server Management Utility .............................. 10–6
10.5  OpenVMS Registry Security ............................................ 10–6
10.5.1  OpenVMS Security Model ........................................... 10–7
10.5.1.1  Granting OpenVMS Registry Access Rights Using the AUTHORIZe Utility ........................................... 10–8
10.5.2  Windows NT Security Model ........................................ 10–9
10.6  Controlling the OpenVMS Registry Server Operations ............. 10–9
10.6.1  Defining Maximum Reply Age/Age Checker Interval Settings .... 10–9
10.6.2  Defining the Database Log Cleaner Interval/Initial Log File Size Settings ........................................ 10–9
10.6.3  Defining Default File Quota/File Quota Interval Settings .......... 10–10
10.6.4  Defining the Scan Interval Setting .................................. 10–10
10.6.5  Defining the Log Registry Value Error Setting .................... 10–10
10.6.6  Defining the Operator Communications Interval Setting .......... 10–11
10.6.7  Defining the Process Time Limit Setting ........................... 10–11
10.6.8  Defining the Reply Log Cleaner Interval Setting .................. 10–11
10.6.9  Defining Snapshot Interval/Snapshot Location/Snapshot Versions Settings ........................................ 10–11
10.6.10  Defining the Write Retry Interval Setting ......................... 10–12

11  OpenVMS Registry System Management

11.1  Installing the OpenVMS Registry ...................................... 11–1
11.2  Configuring the OpenVMS Registry: the REG$CONFIG Configuration Utility ........................................ 11–1
11.2.1  Configuring OpenVMS Registry Values .............................. 11–3
11.3  Starting the OpenVMS Registry ......................................... 11–5
11.3.1  Starting the OpenVMS Registry Manually .......................... 11–6
11.4  Shutting Down the OpenVMS Registry ................................ 11–6
11.5 OpenVMS Registry Server Commands ........................................... 11–6
SHOW SERVER REGISTRY_SERVER ........................................... 11–7
SET SERVER REGISTRY_SERVER ............................................. 11–8
11.6 OpenVMS Registry Failover in a Cluster ........................................... 11–9
11.6.1 Changing the Priority of OpenVMS Registry Server Processes .......... 11–9
11.7 Connecting to the OpenVMS Registry from a Windows NT System ........... 11–9
11.8 OpenVMS Registry Quotas .................................................... 11–10
11.9 OpenVMS Registry Security .................................................. 11–10
11.10 Backing Up and Restoring the OpenVMS Registry Database ................... 11–11
11.11 Using the OpenVMS Registry in an OpenVMS Alpha Mixed-Version Cluster .......................................................... 11–11
11.12 Internationalization and Unicode Support ...................................... 11–11

12 OpenVMS Registry Server Management

12.1 Managing the OpenVMS Registry Server from the Command Line ........... 12–1
12.2 Backing Up and Restoring the OpenVMS Registry Database ................... 12–3
12.2.1 Creating a Snapshot of the OpenVMS Registry Database ................. 12–3
12.2.2 Restoring a Snapshot of the OpenVMS Registry Database ................. 12–3
12.3 OpenVMS Registry Server Management Utility Syntax .......................... 12–4
CREATE DATABASE ..................................................... 12–5
CREATE KEY ...................................................... 12–6
CREATE SNAPSHOT .................................................. 12–8
CREATE VALUE .................................................... 12–9
DELETE KEY ...................................................... 12–11
DELETE VALUE .................................................... 12–12
EXPORT .......................................................... 12–13
IMPORT .......................................................... 12–14
LIST KEY ......................................................... 12–16
LIST VALUE ....................................................... 12–18
MODIFY KEY ...................................................... 12–20
MODIFY VALUE .................................................... 12–22
MODIFY TREE ..................................................... 12–24
SEARCH KEY ....................................................... 12–25
SEARCH VALUE ..................................................... 12–26
SHOW .......................................................... 12–27
START MONITORING .................................................. 12–28
STOP .......................................................... 12–29
ZERO COUNTERS .................................................. 12–30

13 OpenVMS Registry System Services

$REGISTRY and $REGISTRYW .................................................. OR–2
Part III  OpenVMS Events

14  OpenVMS Events

14.1  What are Events? ............................................ 14–1
14.1.1  Suggested Reading ........................................ 14–1
14.2  Overview of OpenVMS Events ............................... 14–2
14.2.1  Viewing OpenVMS Events Using Windows NT Event Viewer ..... 14–2
14.2.2  Viewing OpenVMS Events Using Advanced Server for OpenVMS Event Viewer ........................................ 14–2
14.2.3  Event Logging on OpenVMS Only .......................... 14–2
NTASEVENTW ............................................ 14–4
14.3  Writing Your Own Events .................................. 14–9
14.4  Troubleshooting OpenVMS Events .......................... 14–9

Part IV  Appendixes

A  MIDL Compiler Options

A.1  Mode ......................................................  A–1
A.2  Input ...................................................... A–1
A.3  Output File Generation .................................... A–1
A.4  Output File Names ....................................... A–1
A.5  C Compiler and Preprocessor Options ....................... A–2
A.6  Environment .............................................. A–2
A.7  Error and Warning Messages ............................... A–3
A.8  Optimization ............................................. A–3
A.9  Miscellaneous ............................................ A–3

B  Troubleshooting

B.1  RPC Troubleshooting ....................................... B–1
B.2  Troubleshooting the ACME server .......................... B–3
B.3  Troubleshooting the DCOM$RPCSS Process ................ B–4
B.4  Troubleshooting the Advanced Server for OpenVMS ........ B–5
B.5  Troubleshooting COM for OpenVMS Application Failures .... B–5
B.5.1  Access Denied Failures ................................ B–5

C  Cookbook Examples: Building a Sample Application on OpenVMS

C.1  COM Example (Sample1) .................................. C–1
C.1.1  OpenVMS Instructions .................................. C–1
C.1.1.1  Building the Application on OpenVMS ................. C–1
C.1.1.2  Registering the Application on OpenVMS ............. C–2
C.1.1.3  Running the Application on OpenVMS as an Out-of-Process Server ........................................ C–2
C.1.1.4  Running the Application on OpenVMS and Specifying a Remote Server ........................................ C–2
C.1.1.5  Running the Application on OpenVMS as an In-Process Server ........................................ C–3
C.1.2  Windows NT Instructions ................................ C–3
C.1.2.1  Building the Application on Windows NT ............. C–3
C.1.2.2  Registering the Application on Windows NT .......... C–4
C.1.2.3  Running the Application on Windows NT ............. C–4
C.2  Automation Example (Dispatch_Sample1) .................. C–4
Figures

3–1  OpenVMS Infrastructure and COM for OpenVMS .........................  3–2

B–1  RPC Errors ........................................................................... B–1
Preface

Intended Audience

This document is designed primarily for developers who want to use OpenVMS infrastructure to develop applications that move easily between the OpenVMS and Windows NT environments. These developers include the following:

• COM for OpenVMS developers: those who are encapsulating existing OpenVMS applications or data, as well as those who are creating new COM applications for OpenVMS systems.

• OpenVMS Registry developers: those who want to use the OpenVMS Registry to store information about their OpenVMS systems alone, or who want to use the OpenVMS Registry as a shared repository for both OpenVMS and Windows NT registry information.

This document is not intended as an introduction to COM or the registry. It assumes that readers are already familiar with object-oriented (OO) concepts and COM development techniques, as well as how the registry works on a Windows NT system. The document does provide pointers to online information about COM and the registry and recommends other books about COM, OO development, and the registry.

Document Structure

This document contains all the information you need to develop COM for OpenVMS applications and use the OpenVMS Registry. The document is divided into the following sections:

• Release notes
  COM for OpenVMS, OpenVMS Registry, and OpenVMS Events release notes.

• Part I
  COM for OpenVMS information, including installing, configuring, and running COM for OpenVMS; how to develop a COM for OpenVMS application. This part also includes information about authenticating users and applications between OpenVMS and Windows NT systems, and information about the Active Template Library (ATL) and how to develop ATL applications on COM for OpenVMS.

• Part II
  OpenVMS Registry information, including OpenVMS Registry overview and concepts, OpenVMS Registry server startup and system management, OpenVMS Registry system services, and OpenVMS Registry server management.

• Part III
  OpenVMS Events information.
Win32 API Calls Shown in Example Code

Win32® API calls shown in example code throughout this document and included on the COM for OpenVMS kit are provided for documentation purposes only.

COM for OpenVMS includes only those Win32 APIs that the COM for OpenVMS software requires. These COM APIs are listed in Appendix F, Lists of Differences, APIs, and Interfaces.

Win32 API calls that are not listed in Appendix F but that appear in examples in this document and in code samples on the COM for OpenVMS kit are provided by software vendors other than Compaq. If you want to use any Win32 APIs on OpenVMS other than those listed in Appendix F, you must purchase those interfaces from an independent software vendor such as Bristol Technologies (www.bristol.com).

How To Order Additional Documentation

Use the following World-Wide Web address find out how to order additional documentation:

www.compaq.com/openvms

To reach the OpenVMS documentation website, click the Documentation link.

If you need help deciding which documentation best meets your needs, call 800-ATCOMPAQ.
Conventions

In this manual, any reference to OpenVMS is synonymous with Compaq OpenVMS.

VMScluster systems are now referred to as OpenVMS Cluster systems. Unless otherwise specified, references to OpenVMS Clusters or clusters in this document are synonymous with VMSclusters.

In this manual, every use of DECwindows and DECwindows Motif refers to DECwindows Motif for OpenVMS software.

The following conventions are also used in this manual:

Ctrl/x
A sequence such as Ctrl/x indicates that you must hold down the key labeled Ctrl while you press another key or a pointing device button.

PF1 x
A sequence such as PF1 x indicates that you must first press and release the key labeled PF1 and then press and release another key or a pointing device button.

Return
In examples, a key name enclosed in a box indicates that you press a key on the keyboard. (In text, a key name is not enclosed in a box.)

In the HTML version of this document, this convention appears as brackets, rather than a box.

... A horizontal ellipsis in examples indicates one of the following possibilities:

• Additional optional arguments in a statement have been omitted.
• The preceding item or items can be repeated one or more times.
• Additional parameters, values, or other information can be entered.

. . . A vertical ellipsis indicates the omission of items from a code example or command format; the items are omitted because they are not important to the topic being discussed.

() In command format descriptions, parentheses indicate that you must enclose the options in parentheses if you choose more than one.

[] In command format descriptions, brackets indicate optional elements. You can choose one, none, or all of the options. (Brackets are not optional, however, in the syntax of a directory name in an OpenVMS file specification or in the syntax of a substring specification in an assignment statement.)

[]] In command format descriptions, vertical bars separating items inside brackets indicate that you choose one, none, or more than one of the options.

{} In command format descriptions, braces indicate required elements; you must choose one of the options listed.

This text style represents the introduction of a new term or the name of an argument, an attribute, or a reason.

In the HTML version of this document, this convention appears as italic text.
Italic text indicates important information, complete titles of manuals, or variables. Variables include information that varies in system output (Internal error number), in command lines (PRODUCER=name), and in command parameters in text (where dd represents the predefined code for the device type).

UPPERCASE TEXT

Uppercase text indicates a command, the name of a routine, the name of a file, or the abbreviation for a system privilege.

Monospace type indicates code examples and interactive screen displays.

In the C programming language, monospace type in text identifies the following elements: keywords, the names of independently compiled external functions and files, syntax summaries, and references to variables or identifiers introduced in an example.

A hyphen at the end of a command format description, command line, or code line indicates that the command or statement continues on the following line.

All numbers in text are assumed to be decimal unless otherwise noted. Nondecimal radices—binary, octal, or hexadecimal—are explicitly indicated.
The release notes in this chapter apply to COM Version 1.1-B for OpenVMS.

1.1 COM for OpenVMS Versions

This section describes the versions of COM for OpenVMS.

• **COM Version 1.0 for OpenVMS**
  This was the first release of COM for OpenVMS that shipped with OpenVMS Version 7.2. COM Version 1.0 for OpenVMS is an unauthenticated implementation that does not utilize NTLM security. This release requires OpenVMS Version 7.2 or later. For a list of security differences between an unauthenticated implementation and an authenticated implementation, see Table 1–1.

• **COM Version 1.1 for OpenVMS**
  This was the second release of COM for OpenVMS that shipped with OpenVMS Version 7.2-1. COM Version 1.1 for OpenVMS is an authenticated implementation that utilizes the NTLM security features that are part of OpenVMS Version 7.2-1. This release requires OpenVMS Version 7.2-1 or later. For a list of security differences between an unauthenticated implementation and an authenticated implementation, see Table 1–1.

• **COM Version 1.1-A for OpenVMS**
  This was the third release of COM for OpenVMS. It is a maintenance release that fixed a number of problems in COM Version 1.1 for OpenVMS.

• **COM Version 1.1-B for OpenVMS** (this release)
  This is the fourth release of COM for OpenVMS. COM Version 1.1-B for OpenVMS provides an option that allows you to choose between running COM applications in the default authenticated mode (using NTLM security features), and running COM applications in an unauthenticated mode. See Appendix E for more information.

  COM Version 1.1-B for OpenVMS also provides the Active Template Library (ATL) Version 3.0 for simpler development of COM applications on OpenVMS. See Chapter 9 for more information.

  As of COM Version 1.1-B for OpenVMS, the DCOM-MIDL license is no longer required.

  For a list of problems fixed since the last release, see Section 1.3.
Table 1–1 Summary of Security Differences

<table>
<thead>
<tr>
<th>Area</th>

1.2 Upgrading from a Previous Version of COM to COM Version 1.1-B for OpenVMS

If you are upgrading from an earlier version of COM for OpenVMS to Version 1.1-B, follow the upgrade instructions in Section 4.3. In addition:

- If you are upgrading from COM Version 1.0, follow the upgrade instructions in Appendix D.
- If you are upgrading from COM Version 1.0 or COM Version 1.1, perform the tasks described in Section 1.2.1 and Section 1.2.2.
- If you are upgrading from COM Version 1.1-A, you do not need to perform any additional tasks.

1.2.1 You Must Repopulate the OpenVMS Registry for COM Version 1.1-B for OpenVMS

Note

If you are upgrading from COM Version 1.1-A for OpenVMS, you do not need to repopulate the OpenVMS Registry.

For COM Version 1.1-B for OpenVMS, you must repopulate the OpenVMS Registry to include security settings. Use the DCOM$SETUP command to display the OpenVMS COM Tools menu, and choose option 3.
1.2 Upgrading from a Previous Version of COM to COM Version 1.1-B for OpenVMS

When you populate the OpenVMS Registry for COM Version 1.1-B for OpenVMS, the system prompts you to confirm the repopulation. You must answer YES each time. For example:

[ Starting to Populate the COM for OpenVMS Registry ]
Populating the Registry for OpenVMS may take up to 15 minutes depending on your system.

Enter Y[ES] to continue: YES
The COM for OpenVMS Registry has already been loaded. This action will overwrite the current COM for OpenVMS values and data.

Enter Y[ES] to continue: YES

Note
Repopulating the OpenVMS registry does not affect the registration of existing COM applications.

1.2.2 Previously Registered Applications That Use Logical Names for the Local Server Path

If you previously registered any COM application using a logical name for the local server path, you must modify (reregister) the application using the actual name for the local server path.

For example, if you used the REGISTER_SIMPLE.COM command procedure to register the “Simple” application under COM Version 1.0 for OpenVMS, you must reregister the “Simple” application using the new REGISTER_SIMPLE.COM command procedure.

Compaq updated the registration command files as of COM Version 1.1-A for OpenVMS.

The system stores the COM application local server path in the OpenVMS Registry as a value data as follows:

"HKEY_CLASSES_ROOT\CLSID\{GUID}\LOCALSERVER32"

Use the following REG$CP command to modify the local server path:

$ MCR REG$CP CREATE VALUE HKEY_CLASSES_ROOT\CLSID\{GUID}\Localserver32 -_\
/TYPE=SZ/DATA=device:[directory]image-name.EXE

A GUID is the COM application CLSID. For more information on Localserver32 and CLSID, see Section 7.5.

1.2.3 Changes to the Examples

In COM Version 1.1-A for OpenVMS, the names of the server images in the Dispatch_Sample1 example changed. If you previously built and registered this application and you want to build the new version, you must reregister the server after it has been built.
1.3 Problems Fixed in the Current Release

The following notes describe previously documented problems that have been fixed in COM Version 1.1-B for OpenVMS.

1.3.1 Memory Leak in COM for OpenVMS Servers

In previous versions of COM for OpenVMS, the MIDL compiler generated server proxy code that caused memory to be allocated and not released for certain types of method calls. This resulted in memory leaks in server applications. Testing by Compaq has shown that this problem occurs if the parameter list for any method call includes user defined structures as input parameters, and either FLOAT or DOUBLE datatypes. If you think your COM for OpenVMS server may have this problem, recompile your .IDL file using the new MIDL compiler, recompile the generated files, and relink your application.

If you discovered this problem, you may have compensated for it by deallocating the structures directly, even though COM programming rules state that you do not have to deallocate input parameters. If so, you should remove your workaround and rebuild the application as directed in the preceding paragraph.

1.3.2 DCOM\$RPCSS Process Resource Exhaustion

The COM for OpenVMS run-time environment requires that the DCOM\$RPCSS process is always running.

In previous versions of COM for OpenVMS, Compaq discovered that after DCOM\$RPCSS creates and deletes a large number of COM for OpenVMS application servers, DCOM\$RPCSS can run out of resources. If this happens, DCOM\$RPCSS automatically attempts to restart itself.

This limitation has been corrected.

1.3.3 Passing an Interface Pointer through IDispatch

In previous versions of COM for OpenVMS, passing an interface pointer as a parameter through the IDispatch interface produced an access violation error. This problem has been corrected.

1.4 Known Problems (with Fixes) in the Current Release

The following notes describe the known problems associated with COM Version 1.1-B for OpenVMS. These problems can be corrected by obtaining ECOs or updates from the Compaq Support Centers.

1.4.1 Trusted-Domain Authentication Feature Requires ECO

Compaq has discovered a number of problems associated with COM applications running between systems in different domains with trusts established between the domains. Some of these problems can be corrected by installing the Advanced Server for OpenVMS V7.2-A-ECO1 kit. Please contact your Compaq Support Center and ask for this kit. Other problems that may still occur are listed in the following sections. If you experience these problems, please contact your Compaq Support Center for additional information.
1.4.1 NET3004 Messages Broadcast to Administrator on Windows NT Server System
When COM applications are run between systems in trusted domains, one or both of the systems may report NET3004 errors and broadcast these errors to Windows NT systems logged into the Administrator account. The Administrator will see a popup message box containing the NET3004 error. You can eliminate these broadcasts by stopping the Alerter Service on the Domain Controller that is generating the messages.

1.4.2 Password Synchronization Errors (NET5716, NET5722, NET5723)
Under certain conditions, a Windows NT workstation can lose the ability to authenticate with an Advanced Server domain controller. If this happens you will need to remove the workstation from the domain, then re-add it back to the domain.

1.4.3 Hostmap Problem
Under certain conditions, the hostmap entries in a trusted domain can become invalid. See Section 5.4.6 for a way to resolve this problem.

1.4.4 DCERPC-E-UNKNOWNREJECT Failure (EE128302)
OpenVMS COM clients sometimes report this error when communicating with NT COM components. This is due to a problem in the RPC Runtime. A fix for this problem is available from the Compaq Support Centers. Contact your Support Center and ask for the update to DCE$LIB_SHR.EXE.

1.4.5 DCERPC-E-WHOAREYOUFAILED Failure (EE1282FA)
OpenVMS COM clients sometimes report this error when communicating with NT COM components. This is due to a problem in the RPC Runtime. A fix for this problem is available from the Compaq Support Centers. Contact your Support Center and ask for the update to DCE$LIB_SHR.EXE.

1.4.6 NTARPC-E-PROTOCOL_ERROR Failure (800706C0)
OpenVMS COM clients sometimes report this error when communicating with NT COM components. This is due to a problem in the RPC Runtime. A fix for this problem is available from the Compaq Support Centers. Contact your Support Center and ask for the update to DCE$LIB_SHR.EXE.

1.4.7 Cached IID Value Not Equal to Registry Value Failure
Compaq's testing has shown that OpenVMS processes that run more than 2000 iterations of a COM for OpenVMS application may receive this error. The error is caused by a bug in the Registry client that returns a failure status after a process has made over 16,000 OpenKey requests. A fix for this problem is available from the Compaq Support Centers. Contact your Support Center and ask for the update to SYS$NTA.EXE.

1.4.8 IGNORE_EXTAUTH Support
Support for the IGNORE_EXTAUTH flag in the SECURITY_POLICY SYSGEN parameter is now available in a patch kit from the Compaq Support Centers. Contact your Support Center and ask for the update to VMS$VMS_ACMESHİR.EXE.
1.5 Known Problems (without Fixes) in the Current Release

The following notes describe the known problems associated with COM Version 1.1-B for OpenVMS. These problems currently do not have fixes.

1.5.1 Kernel Threads and Upcalls Not Supported

COM for OpenVMS applications cannot be built with kernel threads or upcalls enabled. This support will be available in a future release.

1.6 Limitations and Restrictions

The following sections contain general release note information.

1.6.1 DCOM$RPCSS Stalls on Restart

If a system running DCOM$RPCSS in a cluster crashes and restarts, the DCOM$RPCSS process may hang during startup. In this condition, the process name remains DCOM$STARTUP-** and the SYS$STARTUP:DCOM$RPCSS.OUT file contains the following error message:

%PPL-W-SYSERROR, system service error  
-SYSTEM-W-VALNOTVALID, value block is not valid

To recover from this condition, stop COM for OpenVMS on each node in the cluster using the following command:

$ @SYS$STARTUP:DCOM$SHUTDOWN

Then restart COM for OpenVMS on each node in the cluster using the following command:

$ @SYS$STARTUP:DCOM$STARTUP

1.6.2 MIDL Limitations and Restrictions

The following release notes pertain to MIDL.

1.6.2.1 MIDL -w Switch

The MIDL compiler allows you to specify either -w or -warn to throttle the level of warnings generated by the compiler. The MIDL compiler for OpenVMS supports only the -w switch.

1.6.2.2 MIDL Compiler Treats wchar_t Literals as char

When using DEC C Version 5.7 or earlier, COM for OpenVMS incorrectly handles wide character literal strings in IDL files. These strings are mishandled as “char” types. (If you are using DEC C Version 6.0 or above, you can disregard this release note.)

For example, suppose an IDL file contains the following string literal:

const wchar_t * PROGRAM_ID = L"Sample.Component";

The MIDL compiler on Windows NT would produce the following macro definition:

#define PROGRAM_ID ( L"Sample.Component" )

However, the MIDL compiler for COM for OpenVMS produces the following by default:

#define PROGRAM_ID ( "Sample.Component" )

The following workarounds are available:

1. Avoid using the DEC C preprocessor if possible.
To run the MIDL compiler without the preprocessor, include the -nocpp or -no_cpp switch on the command line. For example:

```
$ midl -Oicf -nocpp -idcom\$library: server.idl
```

--- Caution ---

Do not use this workaround if the IDL source file or any IDL source file imported by the main IDL source file contains any conditional assembly switches (for example, `#ifdef` . . . `#endif`).

2. Define all character string constants as "char" type instead of "wchar_t" type.
   Using this workaround causes the MIDL compiler on Windows NT and on OpenVMS to create character string constants that are not wide characters. If the software requires a wide character string literal, the software can convert the ANSI string to a wide character string before the value is used.

3. Replace the wide character string constants with macro definitions inside the IDL source file.
   For example, instead of defining the string literal as:
   ```
   const wchar_t * PROGRAM_ID = L"Sample.Component";
   ```
   Use a `#define` inside an IDL `cpp_quote()` directive as follows:
   ```
   cpp_quote("#define PROGRAM_ID L"Sample.Component\"")
   ```
   Even when you use the DEC C preprocessor, the output header file produced by the MIDL compiler for Windows NT and OpenVMS will be as follows:
   ```
   #define PROGRAM_ID L"Sample.Component"
   ```

1.6.2.3 SAFEARRAY Limitation

Because the COM for OpenVMS MIDL compiler is based on Microsoft's MIDL compiler V3.00.44, COM for OpenVMS supports the use of SAFEARRAYs only inside a LIBRARY block in an .IDL file. Microsoft's MIDL compiler V3.00.44 has the same limitation.

1.6.3 DCOM$CNFG Limitations and Restrictions

The following release note pertains to DCOM$CNFG when run in a cluster.

1.6.3.1 DCOM$CNFG Utility and Disabling Applications: Possible Unintended Side Effects

The COM for OpenVMS DCOM$CNFG utility includes several options that allow a developer to modify application properties (for example, changing the location of the computer on which an application can run). If you select one of these options, you are modifying an OpenVMS Registry entry.

Because the OpenVMS Registry supports a single database in a cluster, modifying one of these options affects all nodes in the cluster that are running COM for OpenVMS.

For example, if you use the System-wide Default Properties submenu option 1 to disable COM for OpenVMS, you effectively disable COM for OpenVMS on the entire cluster. In the same way, if you use the Application Location submenu option 1 to prevent an application from running on this computer, you effectively prevent the application from running on any computer in the cluster.
1.6 Limitations and Restrictions

1.6.4 Other Limitations and Restrictions

The following release notes pertain to COM for OpenVMS.

1.6.4.1 Windows 2000 Limitations

Windows 2000 is not supported in COM Version 1.1-B for OpenVMS.

Preliminary results from Compaq's ongoing testing of interoperability between COM for OpenVMS and Windows 2000 indicate that a Windows 2000 client can successfully communicate with a COM for OpenVMS server application. However, authentication problems occur between a COM for OpenVMS client and a Windows 2000 server. Full support for Windows 2000 will be available in a future release.

1.6.4.2 COM Version 1.0 for OpenVMS and COM Version 1.1-B for OpenVMS Not Supported in the Same Cluster

When you install and configure COM Version 1.1-B for OpenVMS on any node in a cluster, you make clusterwide modifications to the OpenVMS Registry that prevent COM Version 1.0 for OpenVMS from running on any other node in the same cluster.

1.6.4.3 Remote Activation of an In-Process Server

If a server component is registered only as an in-process server, the component cannot be activated remotely on OpenVMS. If the system tries to activate an in-process server remotely, the remote client receives a "REGDB_E_CLASSNOTREG (80040154)" error. To activate a server component remotely, the component must be registered as an out-of-process server so the DCOM$RPCSS process can start the component on the client's behalf.

1.6.4.4 Threading Model Supported by COM for OpenVMS

COM Version 1.1-B for OpenVMS supports only the multithreaded apartment (MTA, also known as free threads) model for application servers. The MTA model allows a component to have more than one thread. However, you must ensure that your code is thread safe.

The threading model initialization call is as follows:

```c
CoInitializeEx( 
    NULL, 
    COINIT_MULTITHREADED 
)
```

Because CoInitialize() implies the single-threaded apartment (STA) model, you cannot use it in place of CoInitializeEx() in a server application.

1.6.4.5 SP4 with Enhanced NTLM Enabled is Not Supported

COM Version 1.1-B for OpenVMS supports Windows NT SP4 with the following limitation: COM Version 1.1-B for OpenVMS does not support SP4 with enhanced NTLM enabled.

If you want to use COM Version 1.1-B for OpenVMS with SP4, you must be sure that enhanced NTLM is disabled.

Although SP4 and COM for OpenVMS appear to interoperate with SP4 enhanced NTLM disabled, SP4 has not been fully tested with COM for OpenVMS and is not officially supported.

Compaq's ongoing SP4 testing has identified the following limitation with SP4 and enhanced NTLM disabled: authentication requests fail if you use passwords that are longer than 12 characters.
1.6.4.6 Specifying Activation Security in CoCreateInstanceEx

The pServerInfo parameter of the CoCreateInstanceEx API allows you to specify a username and password that will be used for authentication on the remote server system. The username and password are part of the COAUTHIDENTITY structure inside the COAUTHINFO structure, which is inside the COSERVERINFO structure that is passed as the pServerInfo parameter to CoCreateInstanceEx.

The current NTLM security implementation on OpenVMS does not support this feature for COM client applications on OpenVMS. This feature is supported for COM clients on Windows NT communicating with COM servers on OpenVMS.

1.6.4.7 RPC Communication Failures Caused by Advanced Server

In a cross domain environment, under some load situations, COM applications may report errors that are a side effect of the Advanced Server for OpenVMS having lost a connection between domain controllers. The Advanced Server for OpenVMS reports this error as follows:

NET5719: No domain controller for the domain ‘xxxxx’ is available.

A series of these events over a limited time interval may lead to COM applications reporting RPC communications failures (%x8007071c). In this situation, a stop and start of DCOM$RPCSS may be required to clear the error.

See Section 5.4.6 for more information. If the NET5719 events persist, contact your Compaq Support Center.

1.6.4.8 Specific Error Messages

The following sections list and describe specific COM for OpenVMS error messages.

1.6.4.8.1 RPC Cannot Support Failure (800706E4) If you attempt to use the single-threaded apartment (STA) model, some COM APIs may display the following return status code:

(800706E4)

This model is not supported in COM Version 1.1-B for OpenVMS. For more information, see Section 1.6.4.4.
2.1 Release Notes

The information in the following sections applies to this release.

2.1.1 No Key Change Notifications When a Key’s Attributes are Modified

When you specify the REG$M_CHANGEATTRIBUTES value for the REG$_NOTIFYFILTER item code, the system should notify you of any changes to that OpenVMS Registry key. However, when you modify the attributes of a OpenVMS Registry key, the system fails to notify the processes that have requested notifications.

To correct this problem, specify a different value for the REG$_NOTIFYFILTER item code: use either REG$M_CHANGENAME or REG$M_CHANGELASTSET.

2.1.2 Database Searches Limited

The REG$CP server management utility SEARCH command and calls to the $REGISTRY system service using the REG$FC_SEARCH_TREE_DATA, REG$FC_SEARCH_TREE_KEY, or REG$FC_SEARCH_TREE_VALUE function codes may result in more data being returned to the client than the communications buffers on the client node can handle. These functions are limited to paths that are no more that 16 levels deep and return data of no more than 4 KB.

To avoid this problem, limit the search depth by specifying an exact path—that is, avoid searching the entire database when the database is large.

This restriction will be lifted in a future release.

2.1.3 Key Access Policy

When a user requests access to an OpenVMS Registry key or value, the OpenVMS Registry validates the specified key path by checking the first key and the last key of the key path.

2.1.4 OpenVMS Registry Maximum Data Size Restrictions

The maximum size of any single block of data that can be sent to the OpenVMS Registry server for storage in the OpenVMS Registry database is limited to no more than 7880 bytes. If you exceed this limit, the system displays the following error:

REG-F_NORESPONSE, registry server failed to respond within allotted time period

This limit is imposed by the communication protocol between the OpenVMS Registry server and the OpenVMS Registry client which limits the transfer to 8 K bytes.

This restriction will be lifted in a future release.
2.1.5 REG$_EXQUOTA Errors

If you set the OpenVMS Registry File Quota to be less than the current size of the OpenVMS Registry database, the system displays the following error for all OpenVMS Registry operations:

REG-E-EXQUOTA, registry file quota or page file quota exceeded

Note
You will not see this error message on a single delete operation that brings the size of the OpenVMS Registry database file within quota limits.

As a workaround, you can raise the File Quota temporarily above the current size of the OpenVMS Registry database file, then perform delete operations to bring the OpenVMS Registry database file size within the desired File Quota limit. (For information about changing these quotas, see Section 10.6.3.)

To determine the approximate number of bytes applied towards the two OpenVMS Registry File Quotas, multiply the size of the SYS$REGISTRY:REGISTRY$LOCAL_MACHINE.REG and SYS$REGISTRY:REGISTRY$USERS.REG files by 512. The result of this calculation gives you the approximate number of bytes applied towards quota for each file. For information about how to set OpenVMS Registry file quotas, see Section 2.1.6.

This restriction will be lifted in a future release.

2.1.6 OpenVMS Registry Maximum Database Size Restrictions

The maximum amount of data that can be stored in the OpenVMS Registry database is limited to approximately 1.7 MB. If you exceed this limit, the system displays the following error:

REG-F-DBACCESS, cannot access registry database object

This is a fatal error and prevents further access to the OpenVMS Registry database.

To prevent the REG-F-DBACCESS error, Compaq recommends that you establish quotas to limit the database size so that the OpenVMS Registry can never reach 1.7 MB.

You can establish quotas using either of the following procedures:

• Modify the Default File Quota value.
  Use the following command to set the Default File Quota value:

$ mcr reg$cp modify value/name="Default File Quota"/type=dword -$_$/data=%D1700000 *hkey_local_machine\system\registry\File Quotas*

• Create or modify the File Quota value on individual OpenVMS Registry database files.
  Use the following command to set individual File Quota values:

  Note
  If you have previously set File Quota values, use the MODIFY command in place of the CREATE command in the following examples.
You must specify a value for the /DATA qualifier that is between 32,000 and 2,000,000 (0x7D00 and 0x1E8480 hexadecimal).

If you set a value below 32,000, the system will ignore the value and instead use the Default File Quota value of 10,000,000. This Default File Quota value is too high.

If you set a value above 2,000,000, the system generates a REG-F-DBACCESS error when the OpenVMS Registry database size exceeds that value.

A fix for this problem is available from the Compaq Support Centers. Contact your Support Center and ask for the update to REGISTRY$SERVER.EXE.
The following chapters provide an overview of COM for OpenVMS, provide instructions for installing and configuring COM for OpenVMS and related software, and describe and explain how to create COM applications using COM for OpenVMS.
3

Overview of COM for OpenVMS

3.1 What is COM?

Component Object Model (COM) is a technology from Microsoft that lets developers create distributed network objects. First introduced by Microsoft in its Windows 3.x product, COM was initially called Object Linking and Embedding (OLE). COM provides a widely available, powerful mechanism for customers to adopt and adapt to a new style multivendor distributed computing, while minimizing new software investment.

Digital Equipment Corporation (now Compaq Computer Corporation) and Microsoft jointly developed the COM specification. First released as NetOLE (Network OLE) and then renamed DCOM (Distributed COM), the COM specification now includes network functionality. That is, COM now supports distributed network objects.

COM is an object-based programming model designed to promote software interoperability. COM allows two or more applications (or components) to cooperate with one another easily, even if the objects are written by different vendors at different times and in different programming languages, or if they are running on different machines with different operating systems. To support its interoperability features, COM defines and implements mechanisms that allow applications to connect to each other as software objects.

COM implementations are available on Windows NT, Windows 95™, Windows 98, OpenVMS, and Compaq Tru64™ UNIX®, as well as other UNIX platforms.

3.1.1 Suggested Reading

The following resources can provide you with more information on COM and related topics:

- Third-party books on COM:
    The examples in this document are taken from Dale Rogerson’s book and are used with the publisher’s permission.
    (See Appendix H for a special offer on this book.)
    (See Appendix H for a special offer on this book.)
Overview of COM for OpenVMS

3.1 What is COM?

Provides a good introduction to DCOM and COM, and discusses COM implementations on various platforms.

(See Appendix H for a special offer on this book.)

• Websites:
  — The Component Object Model Specification, available from the Microsoft COM website:
    www.microsoft.com/com

3.2 Overview of COM for OpenVMS

COM for OpenVMS is Compaq's implementation of Microsoft's Windows NT 4.0 Service Pack 3 (SP3) Component Object Model (COM) software on the OpenVMS Alpha operating system.

In support of COM for OpenVMS, Compaq ported Windows NT infrastructure to OpenVMS, including a registry, event logger, NTLM security, and Win32 APIs. COM for OpenVMS is layered on The Open Group's Distributed Computing Environment (DCE) RPC. COM for OpenVMS supports communication among objects on different computers on a local area network (LAN), a wide area network (WAN), or the Internet. COM for OpenVMS is important to the Affinity for OpenVMS program because it delivers a key piece of connectivity with Windows NT.

Figure 3–1 shows the OpenVMS infrastructure.

Figure 3–1 OpenVMS Infrastructure and COM for OpenVMS
In Figure 3–1 the key pieces of the OpenVMS infrastructure are as follows:

**Windows NT system**
The smaller box on the left side of Figure 3–1 represents the Windows NT system.

**OpenVMS Cluster/OpenVMS identity**
The large box on the right side of Figure 3–1 represents the OpenVMS system. Within and around this box you can see several other boxes labeled with numbers. The following list describes these numbered items:

1. **OpenVMS security**
   This is the standard OpenVMS security (login, authentication, ACLs, and so on) available with all OpenVMS systems.

2. **Advanced Server for OpenVMS**
The Advanced Server for OpenVMS provides authentication of Windows NT users to OpenVMS and provides a connection to the OpenVMS Registry and events viewer for Windows NT users.

3. **Windows NT identity/Win32 APIs**
   The OpenVMS Security, MSV1_0 ACME agent, Advanced Server for OpenVMS, OpenVMS Registry, event logger, and Win32 APIs (COM APIs) all contribute to the creation of a Windows NT identity within the OpenVMS system.

4. **OpenVMS Registry**
The OpenVMS Registry, like the registry on Windows NT systems, allows you to store system, software, and hardware configuration information on OpenVMS. COM for OpenVMS uses the OpenVMS Registry to store information about COM applications. For detailed information about the OpenVMS Registry, see Part II of this document.

5. **Event logger**
   Like the event logger on Windows NT systems, the event logger on OpenVMS records informational, warning, and error messages about COM events. For detailed information about the OpenVMS Events, see Chapter 14.

6. **Windows NT COM stack**
   On the Windows NT system, COM requests and responses pass through the COM, RPC, SSPI (security), and Domain layers.

7. **OpenVMS COM stack**
The OpenVMS system mirrors the Windows NT COM stack, with some additions. On the OpenVMS system, COM requests and responses pass through the COM, RPC, SSPI (security), MSV1_0 ACME agent, and Advanced Server for OpenVMS layers. The MSV1_0 ACME agent (shown as ACME in Figure 3–1) is an extension to the Authentication and Credential and Management (ACM) authority. Authentication is explained in detail in Chapter 8.

8. **Connection through RPC layer**
The COM connection between the Windows NT system and OpenVMS is always through the RPC layer.
Overview of COM for OpenVMS

3.2 Overview of COM for OpenVMS

For developers, the COM for OpenVMS developer’s kit provides a Microsoft Interface Definition Language (MIDL) compiler and C-style header files for application development. For more information about the OpenVMS MIDL compiler, see Section F.1.4.1.

OpenVMS now includes a function to get Windows NT credentials. For more information about getting Windows NT credentials through NTA$LOGON, see Section 5.1 and Chapter 8.

COM for OpenVMS also provides a free run-time environment on OpenVMS Alpha for the deployment of COM for OpenVMS client and server applications.

You can find a complete description of Microsoft’s COM, including protocol specifications and programming documentation, at the Microsoft COM website at the following location:

www.microsoft.com/com

The COM for OpenVMS implementation is a subset of the full Microsoft COM implementation. For a complete list of the COM for OpenVMS APIs, supported interfaces, and implementation differences, see Appendix F.

While general interest in COM continues to grow, COM remains a sophisticated technology. It is not aimed at the naive user, but rather at skilled programmers, such as independent software vendors (ISVs) and large management information system (MIS) shops.

3.2.1 How COM for OpenVMS Uses the OpenVMS Registry

COM for OpenVMS requires the OpenVMS Registry. Like its registry database counterpart on Windows NT systems, the OpenVMS Registry stores information about COM applications—specifically those COM applications running on OpenVMS. These COM for OpenVMS applications use the OpenVMS Registry to store CLSIDs (class IDs), startup information, security settings, and so on in the OpenVMS Registry database. COM for OpenVMS uses the Win32 APIs implemented on OpenVMS to read and write this information to the OpenVMS Registry.

COM for OpenVMS requires access to the OpenVMS Registry database. If COM for OpenVMS cannot access the OpenVMS Registry, COM for OpenVMS will not start. For more information about the OpenVMS Registry, see Chapter 10.

3.3 Using COM for OpenVMS

You can use COM for OpenVMS to do the following:

• Develop new COM for OpenVMS COM applications

• Encapsulate existing applications for use with COM for OpenVMS

The following sections discuss new application development and encapsulation in more detail.

An example of a COM application to encapsulate an existing OpenVMS application is included with this release. The example can be found in DCOM$EXAMPLES:[WRAPPER]. A README file describes the example and how to build it.
3.3.1 Developing New Applications

Your organization might use COM for OpenVMS to develop new applications under the following circumstances:

• You want to share data between an OpenVMS server and Windows NT clients in a two-tier client/server computing model.

• You want to share data and to place business logic in the middle tier of a three-tier computing environment. For example, you might have a Windows NT system as the client so you can take advantage of its graphical user interface. You could write business logic as a collection of COM objects on a middle-tier server; while the third-tier large-capacity, high-availability OpenVMS server provides database access.

• You want to share data between one or more OpenVMS systems or between OpenVMS and other non-Windows systems using COM.

The advantages of using COM for OpenVMS include:

• COM for OpenVMS provides a good programming model for programmers with C++ and object-oriented programming skills.

• COM for OpenVMS provides multivendor interoperability. COM is a standard with implementations available on a number of platforms today, and ports for additional platforms are in development.

• The COM for OpenVMS run-time provides automated data marshaling and unmarshaling.

• COM provides OLE Automation services to support communications with Microsoft Visual Basic® applications. Visual Basic is a very popular programming environment for client/server computing.

• COM provides version support for components so you can upgrade applications over time without breaking existing environments.

See Chapter 7 and Appendix C for examples of developing COM for OpenVMS applications.

3.3.2 Encapsulating Existing Applications

If you have monolithic applications written in procedural languages (such as Fortran and COBOL) with character-cell interfaces, you can put a COM “wrapper” or jacket around these applications to allow them either to run on new platforms or to remain on OpenVMS and run in a client/server environment.

The risk associated with completely reengineering some older applications is high. Many applications are large, complex, poorly documented, and not well understood by their current maintainers. Encapsulating a legacy application can be less risky than reengineering and can be the first step in a rewrite. Over time, pieces of the legacy application can be rewritten, while the older version of the application remains stable and available. Encapsulation also allows developers to reuse code, saving time and resources.

Disadvantages to encapsulation include more complex maintenance efforts and the inability to make changes to the underlying code. If the legacy application was unstable or hard to maintain, the encapsulated application will not be any better, and might be made worse because of the wrapper.
Overview of COM for OpenVMS
3.3 Using COM for OpenVMS

There are several layers of a traditional procedural application that you can encapsulate: the user interface (UI), the database, and the data manipulation routines.

— User interface

If you choose to encapsulate the user interface, the UI could be supported on some other platform (for example, from a graphical user interface [GUI] on a Windows NT system).

Encapsulating and moving the UI to the user’s desktop can mean that the rest of the application remains on OpenVMS. Batch processing programs are well suited to user interface encapsulation. Applications that do screen management (for example, SMG or FMS) could have their older character-cell interface encapsulated using COM for OpenVMS, providing users access through newer Windows NT style dialog boxes.

— Database

If you choose to encapsulate a database using COM for OpenVMS, the database could be accessed from parts of a distributed application running on other platforms. The advantage of this approach is that the programmer can keep the database on OpenVMS (a stable, 24x365 system), while the user interface and data access routines are on remote (and perhaps less reliable) systems.

— Database manipulation routines

If you choose to encapsulate the database manipulation routines, the routines could be accessed from any other COM component in a heterogeneous computing environment.

Encapsulating an OpenVMS application using COM for OpenVMS means that you write a COM for OpenVMS server that talks to the application being encapsulated. The COM for OpenVMS server passes arguments to the application in the order and format that the application expects. The COM for OpenVMS server then intercepts the output from the application and directs it to the display device, user interface, or other routines.
This chapter provides a list of the contents of the COM for OpenVMS kit, a list of prerequisite software, and preinstallation requirements. It also describes how to install COM for OpenVMS and includes postinstallation instructions.

4.1 Contents of the COM Version 1.1-B for OpenVMS Kit

COM Version 1.1-B for OpenVMS contains the following:

- Software
  - COM for OpenVMS Run-Time libraries
  - COM for OpenVMS MIDL compiler and header files
  - COM for OpenVMS configuration utilities
  - Active Template Library Version 3.0
  - Sample applications

- Documentation
  - OpenVMS Connectivity Developer Guide (in PostScript, HTML, and PDF formats)

4.2 Prerequisites

The following software is required:

- For OpenVMS systems
  - OpenVMS Version 7.2-1 or higher
  - For COM for OpenVMS application development:
    - DEC C Version 5.6 or higher and DEC C++ Version 5.6 or higher
    - To build ATL applications on OpenVMS:
      - Compaq C++ Version 6.2-016 or higher
  - DIGITAL TCP/IP Services for OpenVMS Version 5.0 or equivalent
  - DECwindows Motif® (see Section 4.2.1)
  - Advanced Server for OpenVMS Version 7.2A or higher
    - (Advanced Server for OpenVMS is not required if you are running COM for OpenVMS in unauthenticated mode.)
  - Before installing COM for OpenVMS check that you have the required free global pages, global sections, and disk blocks. The following table lists the requirements.
Installing the COM for OpenVMS Kit

4.2 Prerequisites

<table>
<thead>
<tr>
<th>Software</th>
<th>Global pages</th>
<th>Global sections</th>
<th>Disk blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>COM for OpenVMS</td>
<td>11,000</td>
<td>27</td>
<td>57000</td>
</tr>
<tr>
<td>RPC Runtime</td>
<td>3,300</td>
<td>14</td>
<td>N/A</td>
</tr>
</tbody>
</table>

For Advanced Server requirements: See the Advanced Server for OpenVMS Server Installation and Configuration Guide.
For TCP/IP requirements: See the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration document.

- For Windows® NT™ systems
  - Windows NT 4.0 with Service Pack 3 or higher installed
  - Microsoft® Visual C++ or Visual Basic (for Windows NT client development and information about MIDL compiler). See the Microsoft website for compiler version requirements.
  - TCP/IP enabled (needed for OpenVMS connectivity)

4.2.1 DECwindows Motif Required to Run COM for OpenVMS

You must install DECwindows Motif for OpenVMS on any system running COM for OpenVMS. If you already have DECwindows Motif installed on your system, you do not need to do anything else. If you do not have DECwindows Motif installed on your system, you can find the installation kit for DECwindows Motif on the OpenVMS Version 7.2-1 CD-ROM in the [KITS.DWMOTIF125_KIT] directory.

**Note**
If you are installing DECwindows Motif to meet the COM for OpenVMS requirements only, you do not need the DW-MOTIF license.

4.3 Supported COM for OpenVMS Installations

The following sections describe COM Version 1.1-B for OpenVMS installation and upgrade options.

**Note**
If you want to run COM Version 1.1-B for OpenVMS in unauthenticated mode, see Section E.1.

<table>
<thead>
<tr>
<th>If you want to do this</th>

4.4 Installing COM for OpenVMS on an OpenVMS Standalone System

Use the following procedure:

1. Install OpenVMS Version 7.2-1. For this procedure, see the OpenVMS Alpha Version 7.x Upgrade and Installation Manual.

2. Install TCP/IP. For this procedure, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier’s documentation.

3. Boot the installed system from the system disk.

4. Install COM Version 1.1-B for OpenVMS. For this procedure, see Section 4.9.

5. Install Advanced Server for OpenVMS. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

6. Configure TCP/IP (set up for startup and reboot); start TCP/IP. You must configure the PWIP driver for Advanced Server for OpenVMS to use TCP/IP. For information about configuring TCP/IP, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier’s documentation.

7. Configure the OpenVMS Registry as follows:
   • Run REG$CONFIG.COM to configure the OpenVMS Registry. See Section 11.2.
   • Edit the SYLOGICALS.COM file to define the SYS$REGISTRY logical as follows:
     $ DEFINE/SYSTEM SYS$REGISTRY directory-specification

8. Start OpenVMS Registry by running the REG$STARTUP.COM file.

9. If you want to run DCE, start DCE now.

   ____________________________ Note ____________________________

   You do not need DCE to run COM for OpenVMS, but if your environment uses DCE, Compaq recommends that you start DCE now.

   ____________________________

   For this procedure, see the DIGITAL DCE Installation and Configuration Guide.
   For more information about OpenVMS external authentication, see Section 5.1.

10. Configure Advanced Server for OpenVMS. You need to reboot to finish Advanced Server for OpenVMS configuration. You must reboot 0 to n times, depending on your system configuration. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

11. Start Advanced Server for OpenVMS (set up for startup on reboot). For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

12. Start the ACME server. Use the following command:

   $ @SYS$STARTUP:NTA$STARTUP_NT_ACME
13. Start RPC. Use the following command:

   $ @SYS$STARTUP:DCE$RPC_STARTUP.COM

14. Configure COM for OpenVMS. For this procedure, see Section 4.10 and Section 6.2.
   - Populate the OpenVMS Registry. For this procedure, see Section 6.2. Use option 3 to populate the OpenVMS Registry database.
   - Create any OpenVMS and Advanced Server for OpenVMS accounts needed by the COM for OpenVMS Service Control Manager. For more information, see Section 6.2. Use option 8 to create the accounts.

15. Edit the SYLOGICALS.COM file and add the following line:

   $ DEFINE DCOM$TO_BE_STARTED TRUE

16. Start COM for OpenVMS. For this procedure, see Section 4.11.

4.5 Upgrading COM for OpenVMS on an OpenVMS Standalone System

Note

Before you start, Compaq recommends that you disable any Advanced Server for OpenVMS, OpenVMS Registry, and layered products automatic startups so these products do not start until you have upgraded COM for OpenVMS and its associated components.

Use the following procedure:

- Edit the SYLOGICALS.COM file to stop the following products from starting:
  - OpenVMS Registry (remove the line DEFINE REG$TO_BE_STARTED TRUE or DEFINE/SYSTEM REG$TO_BE_STARTED TRUE)
  - COM for OpenVMS (comment the line DEFINE DCOM$TO_BE_STARTED TRUE)

- Edit the SYS$STARTUP:SYSTARTUP_VMS.COM file to stop the following products from starting:
  - Advanced Server for OpenVMS (comment the line @SYS$STARTUP:PWRK$STARTUP.COM).

If COM for OpenVMS is currently running, shut down COM for OpenVMS first, Advanced Server for OpenVMS (if running), and then the OpenVMS Registry.

Use the following procedure:

1. Upgrade to OpenVMS Version 7.2-1. For this procedure, see the OpenVMS Alpha Version 7.x Upgrade and Installation Manual.

2. If you need to upgrade TCP/IP, upgrade TCP/IP now. For this procedure, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier’s documentation.

3. Boot the upgraded system from the system disk.

4. Upgrade COM for OpenVMS. For this procedure, see Section 4.9.
Installing the COM for OpenVMS Kit

4.5 Upgrading COM for OpenVMS on an OpenVMS Standalone System

5. Install or upgrade Advanced Server for OpenVMS. You must reboot 0 to n times, depending on your system configuration. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

6. Start TCP/IP unless you have enabled TCP/IP to start on a reboot. For this procedure, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier’s documentation.

7. Start the OpenVMS Registry unless you have enabled the OpenVMS Registry to start on a reboot. For this procedure, see Section 11.2.

8. If you want to run DCE, start DCE now.

Note
You do not need DCE to run COM for OpenVMS, but if your environment uses DCE, Compaq recommends that you start DCE now.

For this procedure, see the DIGITAL DCE Installation and Configuration Guide.
For more information about OpenVMS external authentication, see Section 5.1.

9. Configure Advanced Server for OpenVMS. You must reboot to finish Advanced Server for OpenVMS configuration. You need to reboot 0 to n times, depending on your system configuration. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

10. Start Advanced Server for OpenVMS (set up for startup on reboot). For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

11. Start the ACME server. Use the following command:

```
$ @SYS$STARTUP:NTA$STARTUP_NT_ACME
```

12. Start RPC. Use the following command:

```
$ @SYS$STARTUP:DCE$RPC_STARTUP.COM
```

13. See Appendix D for detailed information about upgrading from COM Version 1.0 for OpenVMS to COM Version 1.1-B for OpenVMS.

14. Configure COM for OpenVMS. For this procedure, see Section 4.10 and Section 6.2.

- Populate the OpenVMS Registry. For this procedure, see Section 6.2. Use option 3 to populate the OpenVMS Registry database.
- Create any OpenVMS and Advanced Server for OpenVMS accounts needed by the COM for OpenVMS Service Control Manager. For more information, see Section 6.2. Use option 8 to create the accounts.

15. Edit the SYLOGICALS.COM file and add the following line:

```
$ DEFINE DCOM$TO_BE_STARTED TRUE
```

16. Start COM for OpenVMS. For this procedure, see Section 4.11.
4.6 Installing COM for OpenVMS on an OpenVMS Cluster

This cluster installation procedure assumes you are installing COM for OpenVMS on a single system disk.

Use the following procedure:

1. Install OpenVMS Version 7.2-1 on all system disks as required. For this procedure, see the OpenVMS Alpha Version 7.x Upgrade and Installation Manual.

2. Install TCP/IP. For this procedure, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier's documentation.

3. Boot the installed system from the system disk.

4. Install COM Version 1.1-B for OpenVMS. For this procedure, see Section 4.9.

5. Install Advanced Server for OpenVMS on this node in the cluster. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

You must install Advanced Server for OpenVMS on at least one Alpha node in the cluster. On the other nodes, you can either install Advanced Server for OpenVMS or select External Authentication images (only).

6. Configure TCP/IP (set up for startup on reboot on each node) and start TCP/IP. You must configure the PWIP driver for Advanced Server for OpenVMS to use TCP/IP. For information about configuring TCP/IP, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier's documentation.

7. Configure the OpenVMS Registry:
   - Run REG$CONFIG.COM to configure the OpenVMS Registry. You need to configure the OpenVMS Registry only once for the cluster. See Section 11.2.
   - Set the SYS$REGISTRY logical to DEFINE/SYSTEM on every Alpha node in the cluster that will run the OpenVMS Registry server.
   - Edit the SYLOGICALS.COM file on every node in the cluster as follows:
     - If the cluster uses a single, cluster-common SYLOGICALS.COM file that is called by each node's SYLOGICALS.COM file, you do not need to make any changes.
     - On those nodes where you do not want the OpenVMS Registry server to run, add the following line to the SYLOGICALS.COM file:
       $$ DEFINE/SYSTEM REG$TO_BE_STARTED FALSE

   Advanced Server for OpenVMS requires that the OpenVMS Registry be running on a node in the cluster.
8. Configure DCE.

Note

You do not need DCE to run COM for OpenVMS, but if your environment uses DCE, Compaq recommends that you start DCE now.

For this procedure, see the DIGITAL DCE Installation and Configuration Guide.

9. If you want to run DCE, start DCE now. You must configure DCE on each node on which you want to run DCE.

For more information about OpenVMS external authentication, see Section 5.1.

10. Configure and start Advanced Server for OpenVMS. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

If this node is running Advanced Server for OpenVMS, set up Advanced Server for OpenVMS for startup on reboot (edit the SYS$STARTUP file as necessary). You must reboot 0 to n times as needed, depending on your system configuration.

If this node is not running Advanced Server for OpenVMS, edit the SYLOGICALS.COM file and define the PWRK$ACME_SERVER logical. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide. For more information about the PWRK$ACME_SERVER logical, see Table 8–2.

11. Start the ACME server. Use the following command:

   $ @SYS$STARTUP:NTA$STARTUP_NT_ACME

12. Start RPC. Use the following command:

   $ @SYS$STARTUP:DCE$RPC_STARTUP.COM

13. Configure COM for OpenVMS. For this procedure, see Section 4.10 and Section 6.2.

   • Populate the OpenVMS Registry. For this procedure, see Section 6.2. Use option 3 to populate the OpenVMS Registry database. You need to populate the OpenVMS Registry only once in a cluster.

   • Create any OpenVMS and Advanced Server for OpenVMS accounts needed by the COM for OpenVMS Service Control Manager. For more information, see Section 6.2. Use option 8 to create the accounts. You need to create these accounts only once in a cluster.

14. Edit the SYLOGICALS.COM file and add the following line:

   $ DEFINE DCOM$TO_BE_STARTED TRUE

15. Start COM for OpenVMS. For this procedure, see Section 4.11.
4.7 Upgrading COM for OpenVMS in an OpenVMS Cluster

Note

This cluster upgrade procedure assumes you are installing COM for OpenVMS on a single system disk.

Note

Before you start, Compaq recommends that you disable any Advanced Server for OpenVMS and layered products automatic startups so these products do not start until you have upgraded COM for OpenVMS and its associated components.

Use the following procedure:

• Edit the SYLOGICALS.COM file to stop the following products from starting:
  — OpenVMS Registry (comment the line DEFINE/SYSTEM REG$TO_BE_STARTED TRUE)
  — COM for OpenVMS (comment the line DEFINE DCOM$TO_BE_STARTED TRUE)

• Edit the SYS$STARTUP:SYSTARTUP_VMS.COM file to stop the following products from starting:
  — Advanced Server for OpenVMS (comment the line @SYS$STARTUP:PWRK$STARTUP.COM)

If COM for OpenVMS is currently running, shut down COM for OpenVMS first, Advanced Server for OpenVMS (if running), and then the OpenVMS Registry on all nodes in the cluster.

Use the following procedure:

1. Upgrade to OpenVMS Version 7.2-1 on all required system disks. For this procedure, see the OpenVMS Alpha Version 7.x Upgrade and Installation Manual.

2. Upgrade TCP/IP. For this procedure, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier’s documentation.

3. Boot the upgraded system from the system disk.

4. Upgrade to COM Version 1.1-B for OpenVMS. For this procedure, see Section 4.9.

5. Upgrade Advanced Server for OpenVMS on this node in the cluster. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

Note

You must install Advanced Server for OpenVMS on at least one Alpha node in the cluster. On the other nodes, you can either install Advanced
6. Configure TCP/IP (set up for startup on reboot on each node). You must configure the PWIP driver for Advanced Server for OpenVMS to use TCP/IP. For information about configuring TCP/IP, see the DIGITAL TCP/IP Services for OpenVMS: Installation and Configuration manual or your TCP/IP supplier's documentation.

7. Configure the OpenVMS Registry as follows:
   - Run \texttt{REG$CONFIG.COM} to configure the OpenVMS Registry. See Section 11.2. You need to configure the OpenVMS Registry only once for the cluster.
   - Edit the \texttt{SYLOGICALS.COM} file on every node that will run the OpenVMS Registry server to define the \texttt{SYS$REGISTRY} logical. For example:
     \begin{verbatim}
     $ DEFINE/SYSTEM SYS$REGISTRY cluster-visible-directory-specification
     \end{verbatim}

   Edit the \texttt{SYLOGICALS.COM} file on every node in the cluster as follows:
   - If the cluster uses a single, cluster-common \texttt{SYLOGICALS.COM} file that is called by each node's \texttt{SYLOGICALS.COM} file, you do not need to make any changes.
   - On those nodes where you do not want the OpenVMS Registry server to run, add the following line to the \texttt{SYLOGICALS.COM} file:
     \begin{verbatim}
     $ DEFINE/SYSTEM REG$TO_BE_STARTED FALSE
     \end{verbatim}

8. Configure and start Advanced Server for OpenVMS. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide.

   If this node is running Advanced Server for OpenVMS, set up Advanced Server for OpenVMS for startup on reboot (edit the \texttt{SYSS$STARTUP} file as necessary). You must reboot 0 to n times as needed, depending on your system configuration.

   If this node is not running Advanced Server for OpenVMS, edit the \texttt{SYLOGICALS.COM} file and define the \texttt{PWRK$ACME_SERVER} logical. For this procedure, see the Advanced Server for OpenVMS/Server Installation and Configuration Guide. For more information about the \texttt{PWRK$ACME_SERVER} logical, see Table 8–2.

9. Start the ACME server. Use the following command:
    \begin{verbatim}
    $ @SYS$STARTUP:NTA$STARTUP_NT_ACME
    \end{verbatim}

10. Start RPC. Use the following command:
    \begin{verbatim}
    $ @SYS$STARTUP:DCE$RPC_STARTUP.COM
    \end{verbatim}

11. See Appendix D for detailed information about upgrading from COM Version 1.0 for OpenVMS to COM Version 1.1-B for OpenVMS.

12. Configure COM for OpenVMS. For this procedure, see Section 4.10 and Section 6.2.
   - Populate the OpenVMS Registry. For this procedure, see Section 6.2. Use option 3 to populate the OpenVMS Registry database. You need to populate the OpenVMS Registry only once in a cluster.
Installing the COM for OpenVMS Kit

4.7 Upgrading COM for OpenVMS in an OpenVMS Cluster

- Create any OpenVMS and Advanced Server for OpenVMS accounts needed by the COM for OpenVMS Service Control Manager. For more information, see Section 6.2. Use option 8 to create the accounts. You need to create these accounts only once in a cluster.

13. Edit the SYLOGICALS.COM file and add the following line:

   \$ DEFINE DCOM$TO_BE_STARTED TRUE

14. Start COM for OpenVMS on a particular node. For this procedure, see Section 4.11.

4.8 Understanding the COM for OpenVMS Environment

COM for OpenVMS relies on a number of interrelated servers (processes) and operating system images. In most cases, the servers start automatically when you restart the system. (Automatic startup requires that you have installed and configured each component and have made appropriate changes to the SYLOGICALS.COM file.) For more information about starting and configuring the servers, see Section 4.3.

Figure 4–1 shows the relationships and dependencies of the processes and operating system layers.

Figure 4–1  Processes/Layers Relationships
Table 4–1 lists the process names and maps each name to its corresponding server.

**Table 4–1 Process Name to Server Name Mapping**

<table>
<thead>

</tr>
</tbody>
</table>

The following sections list and describe the servers and the layers.

### 4.8.1 COM for OpenVMS Service Control Manager (SCM)

The COM for OpenVMS Service Control Manager enables COM for OpenVMS.

**Process name:** DCOM$RPCSS  
**Requires:** OpenVMS Registry, OpenVMS (RPC and SSPI/NTLM layers)  
**Required by:** COM applications  
**Configured by:** DCOM$SETUP. See Section 6.2.  
**Started by:** DCOM$SETUP, option 4. See Section 6.2.  
**Shutdown procedure:** DCOM$SETUP, option 5. See Section 6.2.

### 4.8.2 OpenVMS Registry Server

The OpenVMS Registry server manages the OpenVMS Registry database.

**Process name:** REGISTRY_SERVER  
**Requires:** None.  
**Required by:** COM for OpenVMS, Advanced Server for OpenVMS  
**Configured by:** REG$CONFIG. See Section 11.2.  
**Started by:** REG$STARTUP. See Section 11.3.1.  
**Shutdown procedure:** SET SERVER REGISTRY_SERVER/EXIT. For more information, see Section 11.4.

### 4.8.3 Advanced Server for OpenVMS Server

The Advanced Server for OpenVMS server provides Windows NT and OpenVMS connectivity.

**Process names:**

- NETBIOS
- PWRK$ADMIN_0
- PWRK$KNBDAEMON
- PWRK/LICENSE_R
- PWRK$LMBROWSER
- PWRK$LMDMN
Installing the COM for OpenVMS Kit

4.8 Understanding the COM for OpenVMS Environment

PWRK$LMMCP
PWRK$LMSRV
PWRK$MASTER
PWRK$MONITOR
PWRK$NBDAEMON

The ACME server requires the PWRK$LMSRV process specifically.

**Requires:** OpenVMS Registry  
**Required by:** ACME server  
**Configured by:** PWRK$CONFIG  
**Started by:** PWRK$STARTUP  
**Shutdown procedure:** PWRK$SHUTDOWN

For more information, see the DIGITAL PATHWORKS for OpenVMS (Advanced Server) Server Migration Guide.

4.8.4 ACME Server

The ACME server controls the granting of credentials.

**Process name:** ACME_SERVER  
**Requires:** Advanced Server for OpenVMS  
**Required by:** OpenVMS (RPC and SSPI/NTLM layers) and OpenVMS Events

**Started:**

- Automatically when the SYLOGICALS.COM file contains the following line:
  `NTA$NT_ACME_TO_BE_STARTED YES`
- You can also start the ACME server manually by entering the following command:
  `$ @SYS$STARTUP:NTA$STARTUP_NT_ACME`

**Shutdown procedure:**

`$ SET SERVER ACME {'EXIT | /ABORT}`

For more information, see Section 8.3.2.

4.8.5 RPC Endpoint Mapper

The RPC endpoint mapper controls authentication and security.

**Process name:** DCE$RPCD  
**Requires:** RPC image  
**Required by:** COM for OpenVMS Service Control Manager, RPC image

**Started by:** OpenVMS

**Shutdown procedure:** Use the following command procedure:

`$ @SYS$STARTUP:DCE$RPC_SHUTDOWN.COM`

For more information, see the DIGITAL DCE for OpenVMS VAX and OpenVMS Alpha manual.
4.8.6 RPC and SSPI/NTLM Layers

The RPC and SSPI/NTLM layers provides remote procedure call and Windows NT-style authentication on OpenVMS.

**Process name:** n/a (part of OpenVMS operating system)

**Requires:** OpenVMS, ACME server

**Required by:** COM for OpenVMS

**Started by:** OpenVMS

**Shutdown procedure:** n/a

4.8.7 OpenVMS Events

The Events layer provides Windows NT-style event logging on OpenVMS.

**Process name:** n/a (part of OpenVMS operating system)

**Requires:** ACME server

**Required by:** COM for OpenVMS

**Started by:** OpenVMS

**Shutdown procedure:** n/a

For more information, see Chapter 14.

4.9 Installing COM for OpenVMS

The COM for OpenVMS installation kit contains a single POLYCENTER Software Installation file. The name of the kit is DEC-AXPVMS-D.COM-V0101-B-1.PCSI. You must install the COM for OpenVMS files on an OpenVMS Alpha Version 7.2-1 system. Please check the prerequisites before installing the kit. See Section 4.2.

To install COM for OpenVMS, invoke the POLYCENTER Software Installation utility using the following command:

```
$ PRODUCT INSTALL /SOURCE=device:[user] DCOM
```

For device[user], specify the device name and directory location of the kit, respectively.

----------------- MIDL compiler license no longer required -----------------

The COM for OpenVMS MIDL compiler no longer requires the DCOM-MIDL license.

----------------- End of license section -----------------

Example 4–1 shows a sample installation.
Installing the COM for OpenVMS Kit

Example 4–1 Sample COM for OpenVMS Installation

$ product install dcom/source=disk:[directory]

The following product has been selected:
  CPQ AXPVMS DCOM V1.1-B Layered Product

Do you want to continue? [YES]

Configuration phase starting ...

You will be asked to choose options, if any, for each selected product and for any products that may be installed to satisfy software dependency requirements.

CPQ AXPVMS DCOM V1.1-B

Copyright Compaq Computer Corporation 2000. All rights reserved.

Do you want the defaults for all options? [YES]

The following software is required to run COM for OpenVMS

- OpenVMS Alpha V7.2-1 or later
  - Includes DCE RPC and OpenVMS Registry
- TCP/IP Services for OpenVMS V5.0 or later (or equivalent product)
- Advanced Server for OpenVMS V7.2A or later

Do you want to continue? [YES]

Do you want to review the options? [NO]

Execution phase starting ...

The following product will be installed to destination:
  CPQ AXPVMS DCOM V1.1-B
  DISKSAXP_72PLUS:[VMS$COMMON.]

4.10 COM for OpenVMS Postinstallation Procedures

After you install the COM for OpenVMS kit, do the following:

1. Verify that the OpenVMS Registry is running. (See Chapter 11.)
2. Verify that the Advanced Server for OpenVMS is running. (See Section 4.8.3 for the Advanced Server for OpenVMS process names.)
3. Verify that the ACME server is running. (See Section 4.8.4 for the name of this process.)
4. Verify that the RPC daemon is running. (See Section 4.8.5 for the name of the process.)
5. Populate the OpenVMS Registry with the required COM for OpenVMS keys and values using the DCOM$SETUP utility, option 3. (See Section 6.2.) You must do this only once on an OpenVMS cluster.
6. Configure the DCOM$RPCSS account using the DCOM$SETUP utility, option 8. (See Section 6.2.1.) You must do this only once on an OpenVMS cluster.
7. Start COM for OpenVMS using the DCOM$SETUP utility, option 4. (See Section 6.2.) You must do this on every node in an OpenVMS cluster.
8. If you want COM for OpenVMS to start automatically when the system reboots, modify the `DEFINE DCOM$TO_BE_STARTED` line in the `SYLOGICALS.COM` file. (See Section 4.11.1.) You must do this on every node in an OpenVMS cluster.

9. Configure COM for OpenVMS security. See Chapter 5.

### 4.11 Starting COM for OpenVMS (COM for OpenVMS Service Control Manager)

Use the following command to start COM for OpenVMS:

```bash
$ @SYS$STARTUP:DCOM$STARTUP
```

Alternately, you can run `DCOM$SETUP` and choose option 4. (See Section 6.2.)

The COM for OpenVMS Service Control Manager can be in one of the following states: initializing/running or not started. Depending on the COM for OpenVMS Service Control Manager state, you will see one of the following messages:

- **If the COM for OpenVMS Service Control Manager is running on this node,** the system reports that the process is already active:

  ```
  DCOM Service Control Manager daemon (DCOM$RPCSS) is active [pid=xxxxxxxx]
  ```

- **If the COM for OpenVMS Service Control Manager is initializing on this node,** the system reports that the process is already active:

  ```
  DCOM Service Control Manager daemon (DCOM$STARTUP-**) is active [pid=xxxxxxxx]
  ```

- **If the COM for OpenVMS Service Control Manager is not started on this node,** the system starts COM for OpenVMS as follows:

  ```
  The OpenVMS Registry server is already started on this node.
  *** DCOM system startup procedure ***
  Starting DCOM Service Control Manager daemon ("DCOM$STARTUP-"**) . . .
  After initialization, the daemon will use process name "DCOM$RPCSS" . . .
  %RUN-S-PROC_ID, identification of created process is xxxxxxxx
  *** DCOM startup successful ***
  *** DCOM Startup Procedure Complete ***
  ```

#### 4.11.1 Starting COM for OpenVMS Automatically after a Reboot

Compaq recommends that you modify the `SYSSMANAGER:SYLOGICALS.COM` command file to control COM for OpenVMS startup.

OpenVMS includes a revised `SYLOGICALS.TEMPLATE` file that includes new startup commands for COM for OpenVMS and related components. Review the “Coordinated Startup” section of this template file and add the appropriate information to your existing startup files.

To have COM for OpenVMS start automatically when the system boots, copy the following line to your `SYLOGICALS.COM` file, uncomment the line, and make sure it is set to `TRUE`:

```bash
$ DEFINE DCOM$TO_BE_STARTED TRUE
```

If you do not set COM for OpenVMS to start automatically when the system boots, you can start COM for OpenVMS using the `DCOM$SETUP OpenVMS COM Tools` menu, option 4 (see Section 6.2).
4.12 Shutting Down COM for OpenVMS (COM for OpenVMS Service Control Manager)

Use the following command to shut down COM for OpenVMS:

```
$ @SYS$STARTUP:DCOM$SHUTDOWN
```

Alternately, you can run DCOM$SETUP and choose option 5. (See Section 6.2.)

The COM for OpenVMS Service Control Manager can be in one of the following states: stopped, running, or initializing. Depending on the COM for OpenVMS Service Control Manager state, you will see one of the following messages:

- If the COM for OpenVMS Service Control Manager is stopped on this node, the system reports that there is nothing to shut down:

  ```
  *** DCOM system shutdown procedure ***
  There is no active DCOM$RPCSS daemon on this system.
  *** DCOM Shutdown Procedure Complete ***
  ```

- If the COM for OpenVMS Service Control Manager is running on this node, the system shuts down the process as follows:

  ```
  *** DCOM system shutdown procedure ***
  ******************************************** Warning ********************************************
  *** Stopping the DCOM Service Control Manager daemon (DCOM$RPCSS) ***
  *** Active DCOM applications will no longer be operational. ***
  Do you want to proceed with this operation (YES/NO/?) [N]?
  Enter Y to continue with the shutdown procedure.
  ```

  **Note** For information about suppressing this confirmation step, see Section 4.12.1.

  The system displays the following messages:

  ```
  Terminating DCOM Service Control Manager daemon (DCOM$RPCSS) . . .
  *** DCOM shutdown successful ***
  *** DCOM Shutdown Procedure Complete ***
  ```

- If the COM for OpenVMS Service Control Manager is initializing on this node, the system shuts down the process as follows:

  ```
  *** DCOM system shutdown procedure ***
  ******************************************** Warning ********************************************
  *** Stopping the DCOM Service Control Manager daemon (DCOM$RPCSS) ***
  *** Active DCOM applications will no longer be operational. ***
  Do you want to proceed with this operation (YES/NO/?) [N]?
  Enter Y to continue with the shutdown procedure. The system displays the following messages:

  ```
  Terminating DCOM Service Control Manager daemon (DCOM$STARTUP-**) . . .
  *** DCOM shutdown successful ***
  *** DCOM Shutdown Procedure Complete ***
  ```
4.12.1 Suppressing the DCOM$SHUTDOWN Confirmation Request

You can suppress the DCOM$SHUTDOWN command confirmation request by specifying the NOCONFIRM parameter. Use the following command:

$ @SYS$STARTUP:DCOM$SHUTDOWN NOCONFIRM

The system displays the following shutdown messages without prompting you to confirm the shutdown:

*** DCOM system shutdown procedure ***
Terminating DCOM Service Control Manager daemon (DCOM$RPCSS) . . .
*** DCOM shutdown successful ***
*** DCOM Shutdown Procedure Complete ***
COM Version 1.1-A for OpenVMS and COM Version 1.1-B for OpenVMS support NTLM (NT LAN Manager) authentication for controlling access to COM objects.

Processes that execute client and server applications must obtain Windows NT credentials in order to be authenticated. Processes created automatically by DCOM$RPCSS to execute server applications obtain Windows NT credentials based on the Registry settings for the server being launched. Interactive processes that are used to execute client and server applications must obtain Windows NT credentials by running the NTA$LOGON utility (see Section 8.2).

This chapter applies to COM for OpenVMS in authenticated mode. See Appendix E for information about running COM for OpenVMS in an unauthenticated environment.

This chapter discusses the following topics:

- How to configure an OpenVMS system for NTLM authentication
- How to acquire Windows NT credentials
- The way security affects COM applications
- The way your domain configuration affects COM applications
- The Application Server run-time environment

5.1 System Configuration

NTLM authentication on OpenVMS is implemented in three major components of the operating system (see Section 4.8).

- ACME server — controls the granting of credentials
- RPC and SSPI — provide remote procedure calls and Windows NT-style authentication
- Advanced Server for OpenVMS — maintains Windows NT accounts and provides mapping of Windows NT accounts to OpenVMS accounts

The ACME server, RPC, and SSPI are installed as part of the OpenVMS operating system and require no special configuration. Advanced Server for OpenVMS must be installed as a layered product and must be configured to support NTLM authentication for COM applications (see Section 4.4).

After installing Advanced Server for OpenVMS, you must create network accounts that will be used to execute COM applications. You must also map the network accounts to OpenVMS accounts.
The Advanced Server ADMINISTER utility is used to create network accounts. For example, to create the network account NTUSER1, use the following command:

$ ADMINISTER ADD USER NTUSER1 /PASSWORD="pppppp" /FLAG=NOPWDEXPIRED

The password is case sensitive, so it is enclosed in quotation marks in order to maintain case. A password without quotation marks is converted to uppercase. By default, network accounts are created with the password pre-expired, thus forcing the user to change the password at the first login. The NOPWDEXPIRED flag overrides this default.

A hostmap entry defines the association between a Windows NT user account and a local OpenVMS user account. When OpenVMS authenticates a Windows NT user, OpenVMS uses the hostmap entry to map the OpenVMS user account to the Windows NT user account and build the local OpenVMS user profile and the Windows NT user profile. If no hostmap entry exists, OpenVMS uses the Windows NT user account name as the local OpenVMS user account name.

Use the Advanced Server for OpenVMS ADMINISTER utility to define hostmap information. For example, to map the network account NTUSER1 to the OpenVMS account VMSUSER1, use the following command:

$ ADMINISTER ADD HOSTMAP NTUSER1 VMSUSER1

If the OpenVMS account does not already exist, you must create the account using the OpenVMS Authorize utility (AUTHORIZE). The OpenVMS account must have the EXTAUTH flag set, or the IGNORE_EXTAUTH flag (bit 11, %X0800) must be set in the SECURITY_POLICY SYSGEN parameter (see Section 5.1). This policy allows the OpenVMS system manager to control which OpenVMS user accounts can be used with Windows NT authentication. For example, to set the EXTAUTH flag for an OpenVMS account VMSUSER1, use the following command. For example:

$ MCR AUTHORIZE MODIFY VMSUSER1 /FLAG=EXTAUTH

5.1.1 LOGINOUT.EXE Use of External Authentication

The EXTAUTH flag also directs LOGINOUT.EXE to use external authentication to authenticate an OpenVMS user during the login process (that is, local, dialup, remote, interactive, and network logins). When you set the EXTAUTH flag, LOGINOUT.EXE uses external authentication, not the password in the SYSUAF.DAT record, to verify the OpenVMS user name and password.

LOGINOUT external authentication always requires that you set the EXTAUTH flag in the SYSUAF account record. Unlike NTA$LOGON and authenticated RPC, you cannot override this requirement using the IGNORE_EXTAUTH flag.

5.1.2 DCE Integrated Login Restriction

A site cannot use both external authentication and the older LGI-callout feature on the same system. If you have an LGI-callout image installed, external authentication is disabled for login purposes. Because DCE integrated login uses the LGI-callout mechanism, OpenVMS does not allow logins using Windows NT-based external authentication if DCE integrated login is enabled.
5.2 Cross-Domain Configuration

You can run a COM application on a system in one domain and have the application authenticated by a system in a second domain.

To configure authentication across Windows NT domains, you must do the following:

1. Set up trust relationships between domains.
   For more information, see the Advanced Server for OpenVMS Server Administrator’s Guide.

2. Set up the HostMapDomains parameter on Advanced Server for OpenVMS domains (see Example 5–1).
   For more information, see the Advanced Server for OpenVMS Server Administrator’s Guide.

3. Set up account hostmap entries between the Windows NT user account and a local OpenVMS user account.

Example 5–1 shows how you can set up the HostMapDomains parameter. In this example, there are two domains: DOMAIN_1 and DOMAIN_2. Domain DOMAIN_2 is running Advanced Server for OpenVMS; domain DOMAIN_1 is a Windows NT domain. The commands in Example 5–1 introduce DOMAIN_2 to DOMAIN_1.

Example 5–1 Sample: Setting Up HostMapDomains

SYSJANE$ show sym regutl
REGUTIL == "$SYS$SYSTEM:PWRK$REGUTIL.EXE"
SYSJANE$ regutl
REGUTIL> SET PARAM /CREATE VMSSERVER HOSTMAPDOMAINS DOMAIN_1
REGUTIL> SHOW VALUE * HOSTMAPDOMAINS
Key: SYSTEM\CurrentControlSet\Services\AdvancedServer\UserServiceParameters
Value: HostmapDomains
Type: String
Current Data: DOMAIN_1

5.3 Acquiring Windows NT Credentials

After the network account and the OpenVMS account have been set up as described in Section 5.1, you can log in to the OpenVMS account using the usual OpenVMS login procedures. You can then acquire Windows NT credentials using the NTA$LOGON utility. For example:

$ MCR NTA$LOGON NTUSER1 "pppppp"

In this format, pppppp is the password you specified when you created the network account. The password is enclosed in quotation marks to preserve case. A password without quotation marks is converted to lowercase. If the user name or password is not specified on the command line, the program prompts the user for the required input (see Section 8.2).

To acquire Windows NT credentials for a network account using NTA$LOGON, you must be logged in to the OpenVMS account that is mapped to the network account. Alternatively, if you are logged in to a different OpenVMS account, you must have the IMPERSONATE privilege and use the /OVERRIDE_MAPPING switch. For example:

$ MCR NTA$LOGON /OVERRIDE_MAPPING NTUSER2 "pppppp"
5.3 Acquiring Windows NT Credentials

To determine whether a process has Windows NT credentials, use the NTA$LOGON utility with the /LIST switch. For example:

$ MCR NTA$LOGON /LIST

5.4 Application Security

The COM security model allows the creation of secure distributed applications. COM security can be enabled by using settings in the OpenVMS Registry and by using COM security APIs and interfaces. There are two primary areas of security that can be applied to COM applications: launch security and activation security.

Launch security and activation security have system default settings; application-specific settings override these defaults. The settings are stored in the Registry and are maintained by using the DCOMCNFG utility on Windows NT and by using the DCOMCNFG option of DCOM$SETUP.COM on OpenVMS. The COM API CoInitializeSecurityEx can be used from within an application to enhance or override the Registry settings.

5.4.1 Launch Security

Launch security determines which network accounts can be used to create, or “launch” server processes. The launch security settings are referenced when a COM request is received on a system that will result in the launching of a server process to satisfy the request. These settings can explicitly or implicitly allow or disallow a user request to launch a server. The DCOM$RPCSS process authenticates the incoming request to determine the identity of the client. If DCOM$RPCSS determines that it needs to launch a server process to satisfy the request, DCOM$RPCSS allows or disallows the launching of the server based on the identity of the client and the launch security settings.

5.4.2 Activation Security

Activation security determines which network accounts can be used to execute method calls in server applications. The activation security settings are referenced when a COM request is received on a system for a method call in an existing server process. The server process authenticates the incoming request to determine the identity of the client. The server process allows or disallows the execution of the method call based on the identity of the client and the activation security settings.

5.4.3 Server Process Identity

A server process created by DCOM$RPCSS on OpenVMS is a detached process that has an OpenVMS identity and follows all the OpenVMS security rules for a detached process. In addition, it has a network identity that is used to enforce the COM security model (see Section 5.5).

COM servers create separate server threads to execute each client request. These server threads have their own OpenVMS identity and network identity, based on the identity of the client. When a server thread is executing a request on behalf of a client, it is the thread’s identities, not the process’ identities, that are used to enforce security.
5.4.4 Domain Issues

Two systems running COM client and server applications can exist in one of three possible domain configurations:

- Systems are in the same domain
- Systems are in separate domains with trusts established between the two domains
- Systems are in separate domains without trusts, or systems are not in a domain

The ability for servers and DCOM$RPCSS to authenticate client requests are affected by the domain configurations. When both systems are in the same domain or when the systems are in separate but trusted domains there is no problem authenticating. The trusted domain configuration is a bit more complex and requires that the trusts and mappings be configured correctly but once configured, there is no trouble authenticating (see Section 5.2).

Systems in separate, nontrusted domains or systems not in any domain cannot be authenticated using the normal mechanisms. To run authenticated COM applications between such systems, you must pass authentication information (user name and password) from the client to the server. COM provides this capability in the CoCreateInstanceEx API. The pServerInfo parameter of the CoCreateInstanceEx API allows you to specify a user name and password to be used for authentication on the remote server system. The user name and password are part of the COAUTHIDENTITY structure, within the COAUTHINFO structure within the COSERVERINFO structure, that is passed as the pServerInfo parameter to CoCreateInstanceEx.

Section C.3 shows how you can authenticate a remote client that is neither in the server’s domain nor in a domain that has a trust with the server’s domain.

The current NTLM security implementation on OpenVMS does not support this feature for COM client applications on OpenVMS. This feature is supported for COM clients on Windows NT that communicate with COM servers on OpenVMS. To run COM client applications on OpenVMS where the server is not in the same domain or in a trusted domain, you must disable authentication for the application, as described in Section 5.4.5.

5.4.5 Disabling Authentication

Under certain conditions, you may want to disable authentication between a client and server applications. This feature disables many of the security features of COM and of the operating system and should not be used in an environment where security is required. There are two ways to disable authentication for COM applications:

- Use DCOMCNFG to change the default authentication level to None on both systems.
- Add a call to CoInitializeSecurity in both the client and server applications and set the dwAuthnLevel parameter to RPC_C_AUTHN_LEVEL_NONE.

The server must be configured to run with a specific NTLM account identity. Since the client will not be authenticated, there is no way for the server to run with a client’s identity. To configure a server to run with a specific NTLM identity, use DCOMCNFG and change the application properties to select the NTLM account.
5.4.6 Access Denied Problems (80070005)

The most common security error a COM application will encounter is access denied (error status value 80070005). The following is a list of the most common causes of this error:

- Client process on OpenVMS does not have Windows NT credentials. Run NTA$LOGON to acquire Windows NT credentials.
- Application-specific launch or access permissions do not allow access. Check the application settings using DCOMCNFG (see Section 6.3.1).
- System default launch or access permissions do not allow access. Check the system defaults using DCOMCNFG (see Section 6.3.6).
- CoInitializeSecurityEx API call is incorrect. Verify that the client and server security calls are valid.
- Server process or thread does not have permission to perform a particular operation. Verify that the OpenVMS identity being used to execute a client request has the necessary privileges to perform the operation.
- Server process does not have access to the server images. Verify that the OpenVMS identity used to launch a server process has read and execute permissions for the server image and any dynamically loaded images (.EXE files).
- Advanced Server hostmap entry problems. In order for NTLM authentication to work correctly, network accounts must be mapped to OpenVMS accounts (see Section 5.1). To verify the mapping of network accounts to OpenVMS accounts, use the ADMINISTER command:

```
$ ADMINISTER SHOW HOSTMAP
```

In a multiple-domain environment with trusts established between domains, cross-domain mappings must be created (see Section 5.2). Under certain conditions, the Advanced Server is unable to verify a user account associated with a hostmap entry. Any attempt to display the hostmap entry of a user name that can not be verified will result in the user name being displayed using its eight-digit hexadecimal internal representation (for example, "DOMAINNAME\000003fd"). If this happens, verify that the Advanced Server is running on each machine. You should also verify the trusts between domains using the following ADMINISTER command:

```
$ ADMINISTER SHOW TRUST
```

If the trusts are valid and the hostmap entries are still displayed with the numeric format, you should shut down and restart the Advanced Server.

5.5 Server Run-Time Environment

When DCOM$RPCSS launches a server in response to a client request for a COM object, DCOM$RPCSS creates a detached process and executes either the server image or server command file in the context of the detached process. The image or command file that is executed is determined by the value of the Registry key HKEY_CLASSES_ROOT\CLSID\{iid\} LocalServer32, where iid is the unique identifier of the COM object.

The run-time environment of the detached process is as follows:

- Default directory
The default directory of the detached process is the same as the default directory of DCOM$RPCSS. This is determined by the default directory of the process that executed the DCOM$STARTUP command file. If DCOM$STARTUP is executed by the system startup procedure, then the default directory will be SYS$SYSTEM.

- **Windows NT identity**
  
  Depends on the application identity setting. This setting is made using DCOMCNFG.
  
  If the application identity is set to "launching user" (the default), then the Windows NT identity of the detached process is the same as the Windows NT identity of the client.
  
  If the application identity is set to a specific NTLM account then the Windows NT identity of the detached process is that of the NTLM account.

- **OpenVMS user name**
  
  The OpenVMS user name of the detached process is the user name that is mapped to the Windows NT identity of the detached process. The mapping of OpenVMS user name to Windows NT identity is established using the Advanced Server ADMINISTER utility (see Section 5.1).

- **OpenVMS privileges**
  
  Depends on the application identity setting. This setting is made using DCOMCNFG.
  
  If the application identity is set to "launching user" (the default), then the privileges depend on the location of the client. If the client is running on the same system as the server, then the privileges of the detached process will match the privileges of the client. If the client is running on a different system from the server, then the privileges of the detached process will be the default privileges of the OpenVMS user name account.
  
  If the application identity is set to a specific NTLM account then the privileges of the detached process will be the default privileges of the OpenVMS user name account.

- **Process logicals**
  
  SYS$INPUT and SYS$OUTPUT are defined to the disk device where the server image or command file is located. For example, if the server image is DKA0:[TEST]CMPNT.EXE, then SYS$INPUT and SYS$OUTPUT are defined to DKA0:. SYS$SCRATCH is not defined.
  
  If these environment settings are not sufficient for the successful execution of your server, then you should explicitly define the environment settings you need. One way to easily set up an environment for your server is to create a command file to run your server, and register the command file, instead of the executable image, as the file to be executed when the server is launched. You can define the environment in the command file prior to executing the server image. For example, if you build SAMPLE1 in the directory DKA0:[SAMPLE1] and register it using the BUILD_SAMPLE1 command file, then the server image will be named DKA0:[SAMPLE1]CMPNT.EXE. The Registry key HKEY_CLASSES_ROOT\CLSID\{0C092C21-882C-A6BB-0080C7B2D682\} LocalServer32 will have a value of DKA0:[SAMPLE1]CMPNT.EXE. You can change the value of that key to DKA0:[SAMPLE1]RUN_CMPNT.COM and create the command file, as follows:
COM for OpenVMS Security
5.5 Server Run-Time Environment

$! RUN_CMPNT.COM
$! Command file to run SAMPLE1
$ set default DKA0:[SAMPLE1]
$ define sys$output DKA0:[SAMPLE1]SAMPLE1.LOG
$ ! Other definitions as needed
$ RUN CMPNT.EXE
$ exit

When DCOM$RPCSS receives a request for SAMPLE1 and launches a server, the server executes this command file in the detached process.
This chapter describes how to configure your OpenVMS system (and, optionally, your Windows NT system) to develop and deploy COM applications. It describes the following COM for OpenVMS utilities:

- The DCOM$SETUP utility, which helps a system manager configure the COM for OpenVMS system environment.
- The DCOM$CNFG utility, which helps an application developer configure and examine COM applications.
- The DCOM$REGSVR32 utility, which allows an application developer to register and unregister in-process server applications.

This chapter also includes information about configuring OpenVMS and Windows NT systems to interoperate.

Before you begin
Before you configure COM for OpenVMS on your OpenVMS system, you must install and configure required components and install COM for OpenVMS. See Chapter 4 for information about these steps.

6.1 DCOM$SETUP Utility

DCOM$SETUP is a collection of tools to help a system manager configure the COM for OpenVMS system environment.

DCOM$SETUP Conventions and Requirements

- For Yes/No questions, you can enter any one of the following:
  - YES or NO
  - Y or N
  - Return (to accept the default value)
- Some DCOM$SETUP options require system manager privileges and OpenVMS Registry access.
6.2 Running DCOM$SETUP

To run DCOM$SETUP, enter @SYS$STARTUP:DCOM$SETUP at the OpenVMS system prompt.

The system displays the OpenVMS COM Tools menu.

Figure 6–1 DCOM$SETUP OpenVMS COM Tools Menu

OpenVMS COM Tools

1) DCOMCNFG, COM Configuration Properties
2) GUIDGEN, Globally Unique Identifier Generator
3) Populate the Registry database for COM
4) Start the COM server
5) Stop the COM server
6) Register a COM application
7) Create the DCOM$GUEST account and directory
8) Configure the DCOM$RPCSS accounts
H) Help
E) Exit

Please enter your choice:

To choose an option, enter the option number. The options are as follows:

• 1) DCOMCNFG, COM Configuration Properties
   Use to query information and manipulate properties of COM for OpenVMS applications. For more information, see Section 6.3.

• 2) GUIDGEN, Globally Unique Identifier Generator
   Generate CLSIDs (class IDs) (or GUIDs [globally unique identifiers]) in various formats (for example, the OpenVMS Registry or Windows NT Registry format). The CLSID tags each application with a unique identifier. This version of DCOM$SETUP generates GUIDs in OpenVMS Registry and Windows NT Registry formats only. For a discussion of other formats, see Section 7.1.

• 3) Populate the Registry database for COM
   Set up the OpenVMS Registry database. COM for OpenVMS requires that specific keys and values be added to the OpenVMS Registry database. You must have both write access to the OpenVMS Registry and Windows NT Administrator privileges.

• 4) Start the COM server
   Start the COM for OpenVMS Server Control Manager server (DCOM$RPCSS). DCOM$SETUP calls the SYS$STARTUP:DCOM$STARTUP procedure to start the server. For more information, see Section 6.2.2.

• 5) Stop the COM server
   Shut down the COM for OpenVMS Service Control Manager server (DCOM$RPCSS). DCOM$SETUP calls the SYS$STARTUP:DCOM$SHUTDOWN procedure to stop the server. For more information, see Section 6.2.2.

• 6) Register a COM application
Register a COM for OpenVMS server application. You can register the following types of servers:

— In-process server
   When you register an in-process server, the system prompts you for the server’s location.

— Local server or out-of-process server
   When you register a local server or out-of-process server, the system prompts you for the following information:
   + Full path information (location of the server)
     This is a required value. Use the following syntax:
     device:[directory]file-name.ext
   + Application title
     This is an optional value. If you do not supply a title, the system uses a default title.
   + CLSID (GUID)
     This is a required value. If the server does not have a CLSID, the system generates one automatically. For more information about CLSIDs and LocalServer32, see Section 7.5.1.

After you complete the registration process, the system generates the following files:

1. A Windows NT Registry file (server-name.REG_NT) that you can use to register the application on a Windows NT system.
2. An OpenVMS command procedure (server-name.REG_VMS) that you can use to register the server on an OpenVMS system.

When you use these files on other systems, you must modify the path statement to point to the server’s current location. For more information, see Section 6.2.3.

- 7) Create the DCOM$GUEST account and directory
   You must create the DCOM$GUEST account before you can use COM for OpenVMS without NTLM authentication.

- 8) Configure the DCOM$RPCSS accounts
   Configure and create the DCOM$RPCSS Advanced Server for OpenVMS user and SYSUAF accounts. The COM for OpenVMS Service Control Manager (DCOM$RPCSS) requires these accounts for authentication. For more information, see Section 6.2.1.

- H) Help
   Display help about each menu option.

- E) Exit
   Exit the menu.
6.2.1 Creating and Configuring DCOM$RPCSS Accounts

To display these functions, choose option 8 from the OpenVMS COM Tools menu. The system displays the following:

```
Configure the COM for OpenVMS Service Control Manager (DCOM$RPCSS) accounts
1) Create the DCOM$RPCSS account in both the SYSUAF database and the
   Advanced Server for OpenVMS SAM database. The password you specify
   for the new DCOM$RPCSS user is stored in a protected file.
2) Update the DCOM$RPCSS user password in the COM for OpenVMS Service
   Control Manager password file.
E) Exit
```

Please enter your choice:

```
Enter one of the following:
• 1) Create the DCOM$RPCSS account . . .
   This option creates the DCOM$RPCSS account in both the SYSUAF database
   and the Advanced Server for OpenVMS SAM database.
   The password you specify for the DCOM$RPCSS user is stored in a protected
   file that the COM for OpenVMS Service Control Manager uses to log into the
   NTLM network and obtain a Windows NT identity.

   Note
   The system creates this account in the Advanced Server for OpenVMS
   database with a password that will not expire. To change this behavior
   (that is, modify the account so that the password expires according to the
   Advanced Server for OpenVMS User Policy), use the following procedure:
   1. Run the Advanced Server for OpenVMS ADMIN utility.
   2. Log into the Administrator account.
   3. Issue the following ADMIN command:
      ```
      ADMIN> MODIFY USER DCOM$RPCSS/FLAG=NODISPWDEXP
      ```
   To determine the maximum password age in the Advanced Server for
   OpenVMS User Policy, enter the following ADMIN command:
      ```
      ADMIN> SHOW ACCOUNT POLICY
      ```
   If you change the Advanced Server for OpenVMS password of the
   DCOM$RPCSS account, you must update the password in the COM for
   OpenVMS Service Control Manager password file. (See option 2 [Update
   the DCOM$RPCSS user password].)
```

Use the following procedure:

1. Enter 1.
   The system displays the following:
To create a new account, you must be logged on to an existing Advanced Server for OpenVMS account that is capable of adding new users.

Enter Y[ES] to log on to this account:

You must belong to the PATHWORKS administrator group to create this account.

2. Enter Y.

The system prompts you to log on. The password is not displayed as you enter it.

Enter username: JOSEPHM
Password: Confirm password:

The system prompts you to enter a new password, and then asks you to confirm the password. The password is not displayed as you enter it.

Enter the new DCOM$RPCSS password.

Enter password: Confirm password:

The system uses this password for both the SYSUAF account (DCOM$RPCSS) and the PATHWORKS user account (DCOM$RPCSS). The system stores this password in the COM for OpenVMS Service Control Manager password file.

The system displays the following account creation information:

%PWRK-S-USERADD, user "DCOM$RPCSS" added to domain "DCOM1_DOMAIN"
Username: DCOM$RPCSS Owner: COM
Account:     UIC:  [37776,1] ([DCOM$RPCSS])
CLI:        Tables: DCLTABLES
Default: SYSSYSDEVICE:[DCOM$RPCSS]
LGICMD:     Flags: ExtAuth
Primary days: Mon Tue Wed Thu Fri
Secondary days:  Sat Sun
No access restrictions
Expiration: (none) Pwdminimum: 6 Login Fails: 0
Pwdlifetime: (none) Pwdchange: (pre-expired)

Authorized Privileges: NETMBX TMPMBX
Default Privileges: NETMBX TMPMBX
%PWRK-S-HOSTMAPADD, user "DCOM$RPCSS" mapped to host user "DCOM$RPCSS"
Press RETURN to continue:

2) Update the DCOM$RPCSS user password . . .

If you change the DCOM$RPCSS user password in the Advanced Server for OpenVMS SAM database, you must also update the password in the COM for OpenVMS Service Control Manager password file.
Use the following procedure:

1. Enter 2.

The system displays the following:

   Enter the new DCOM$RPCSS password.

   Enter password:
   Confirm password:

2. Enter the new password and confirm the password.

   • E) Exit
   Exit the menu.

6.2.2 Starting and Stopping the COM Server (DCOM$RPCSS Process)

COM for OpenVMS requires that the COM server process (DCOM$RPCSS) always be running. The DCOM$RPCSS process on OpenVMS provides the same functions for the COM run-time environment that the RPCSS process provides on Microsoft Windows NT, including the following:

   • Build and maintain the list of server objects running on the system.
   • Build and maintain a cache of known applications as defined in the registry. This cache improves COM performance.
   • Start a server as a detached process whenever a client requests a connection to a server object that is not currently running.
   • Communicate with the RPCSS process on remote Windows NT systems or the DCOM$RPCSS process on OpenVMS systems to locate or start remote server objects.

To start DCOM$RPCSS, either use DCOM$SETUP option 4 (“Start”) (see Section 6.2) or call the COM for OpenVMS startup procedure directly from SYS$STARTUP:DCOM$STARTUP. See Section 4.11 for information on starting COM for OpenVMS.

To stop DCOM$RPCSS on your system, either use the DCOM$SETUP option 5 (“Stop”) (see Section 6.2) or call the COM for OpenVMS shutdown procedure directly from SYS$STARTUP:DCOM$SHUTDOWN. See Section 4.12 for information on shutting down COM for OpenVMS.

6.2.3 Registering an Application

The following example shows how to register the COM for OpenVMS “Simple” application included on the COM for OpenVMS kit. You can use the resulting Windows NT file to register the server on a Windows NT system as long as the application is available on your Windows NT system.

To build the “Simple” application on a Windows NT system, see and execute the instructions in the README-SIMPLE.TXT file in DCOM$EXAMPLES:[SIMPLE].

Note
You must build and compile the application before you can register it. For complete details, see the step-by-step example in DCOM$EXAMPLES:[SIMPLE] included in the COM for OpenVMS kit.
Use the following procedure:

1. From the DCOM$SETUP menu, enter 6 or REGISTER.
2. Answer the questions as follows:

   Note

   The “Simple” application already has a CLSID.

---

**Example 6–1 Sample “Simple” Application Registration on OpenVMS**

Enter server type (1. In-Proc 2. Out-Proc): 2
Enter Local Path (device:\[directory]filename.ext): DKA0:\[SMITH\]SSERVER.EXE
Enter Application Name (<RETURN> to assign default): COM Simple Server
Does the server have a CLSid (GUID) (Yes/No) [N]: Y
Enter the CLSid (i.e. {xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}):
   {5e9ddec7-5767-11cf-beab-00aa006c3606}
Verify Application Information:
   Application Name: COM SIMPLE SERVER
   Local Path: DKA0:\[SMITH\]SSERVER.EXE
   Application ID: {5E9DDEC7-5767-11CF-BEAB-00AA006C3606}
Is the information correct (Yes/No) [Y]:
Register application (Yes/No)? [Y]:

**Example 6–2 Contents of SSERVER.REG_NT**

REGEDIT
HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\ = DCOM server application SSERVER
HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\LaunchPermission = Y
HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\LocalServer32 = DEVICE:\SSERVER

To reregister the “Simple” application on an OpenVMS system, enter the following command at the system prompt:

$ @SSERVER.REG_VMS
Example 6–3 shows the contents of the SSERVER.REG_VMS command procedure:

```plaintext
$ Set noon
$ regcp := $regcp
$ crekey := $regcp create key
$ creval := $regcp create value
$ modval := $regcp modify value
$ lisval := $regcp list value
$ crekey HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}
$ creval HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606} /data="DCOM server application SSERVER" /type=sz
$ creval HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\name="AppID" /data={5E9DDEC7-5767-11CF-BEAB-00AA006C3606} /type=sz
$ crekey HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\LaunchPermission
$ creval HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\LaunchPermission /data="Y" /type=sz
$ crekey HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\LocalServer32
$ creval HKEY_CLASSES_ROOT\CLSID\{5E9DDEC7-5767-11CF-BEAB-00AA006C3606}\LocalServer32 /data="DKA0::[SMITH]SSERVER.EXE" /type=sz
```

6.3 Running DCOM$CNFG

DCOM$CNFG is a utility to help COM developers configure and manage COM for OpenVMS applications on OpenVMS. Use the DCOM$CNFG utility to query information and manipulate properties of COM for OpenVMS applications.

To use the DCOM$CNFG utility, choose option 1 from the DCOM$SETUP menu.

Note

Before running the DCOM$CNFG utility, you must:

- Have OpenVMS Registry Read access to read application properties, and Write access to modify application properties.
- Ensure that the ACME server is running on the current system. The ACME server must be running to view and change application security properties. For more information, see Table 4–1.
- Acquire Windows NT security credentials before you can change an application identity. For more information, see Section 8.2.

The system displays the DCOM$CNFG Main menu.
Figure 6–2  DCOM$CNFG Main Menu

DCOM$CNFG Main

1 - Applications List
2 - System-wide Default Properties
3 - System-wide Default Security

(E to Exit)
(H for Help)

Enter <CTRL-Z> or 'E' to return to the previous menu at any time
Please enter your choice:

The options are as follows:

• 1 - Applications List
  Lists all applications registered on this machine. For more information about
  this option, see Section 6.3.1.

• 2 - System-wide Default Properties
  Allows you to set systemwide machine properties. For more information
  about this option, see Section 6.3.5.

• 3 - System-wide Default Security
  Allows you to set systemwide security parameters. For more information
  about this option, see Section 6.3.6.

6.3.1 The DCOM$CNFG Application List Submenu

To display this submenu, from the DCOM$CNFG Main menu, choose option 1.

The system displays the Applications List submenu.

Figure 6–3  Applications List Submenu

Applications List

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Inside COM, Chapter 11 Example</td>
</tr>
<tr>

<td>...</td>
</tr>
<tr>
<td>(E to Exit to previous menu)</td>
<td></td>
</tr>
<tr>
<td>(H for Help)</td>
<td></td>
</tr>
</tbody>
</table>

Please enter Index number to select an Application:

Enter a number to select an application. You can then view or configure its
properties.

This option displays the Application Properties submenu.

Note: The system stores the Application Properties (Location, Security, and
Identity) (see Figure 6–4) in a special key in the OpenVMS Registry that
is associated with each application. You cannot change the Application Properties until you create this special key using the DCOM$CNFG utility. The DCOM$CNFG utility creates this special key when the utility discovers a newly registered application. In this case, the DCOM$CNFG user must have acquired Windows NT security credentials for an account that is a member of the Administrator group. Otherwise, the key will not be created. For more information about acquiring Windows NT credentials, see Section 8.2).

Use the following procedure to manage the Application Properties:

1. Register the application.
2. Do either of the following:
   - Acquire Windows NT security credentials for an account that is a member of the Administrator group and then run DCOM$CNFG.
   - Have a system administrator with the appropriate credentials run DCOM$CNFG.
3. Run DCOM$CNFG from your own account to manage the properties.

Figure 6–4  Application Properties Submenu

Application Properties
General Properties of this DCOM Application
Application name: Inside COM, Chapter 11 Example
Application id: {0C92C2C-882C-11CF-A6BB-0080C7B2D682}
Application type: local server
Local path: DISK1:[SMITH.DISPATCH_SAMPLE1]CMPNT.EXE
Type Library: {D3011EE1-B997-11CF-A6BB-0080C7B2D682}version: 1.0 DISK1:[SMITH.DISPATCH_SAMPLE1]Server.tlb

1 - Location  Machine to run application

3 - Identity  User account to use to run application

(E to Exit to previous menu)
(H for Help)

Please enter Application Property you wish to change:

If the system cannot find the type library file or if the type library is unaccessible, the system displays an error message next to the type library file name.

The options are as follows:

- 1 - Location: Machine to run application
   This option allows you to set or change the machine on which the COM application will run.
   The system displays the Application Location submenu.
Figure 6–5  Application Location Submenu

The following settings allow DCOM to locate the correct computer for this application. If more than one machine is selected then DCOM uses the first available one. Client applications may override these selections.

Application name:  Inside COM, Chapter 11 Example

1 - Run application on this computer (Yes/No)
   Current value: Yes

2 - Run application on another computer
   Current value: Currently Disabled

(E to Exit to previous menu)
(H for Help)

Please enter your choice:

The options are as follows:

1 - Run application on this computer
   Indicates whether the application will be run on the local computer. Select the option to change the current value.

2 - Run application on another computer
   Indicates that the application will be run on the specified computer. Select the option and enter one of the following:
   + A valid system name to change the current value.
   + A hyphen (-) to disable the value. This sets the field to “Currently Disabled.”

2 - Security: Security permissions for application
   This option allows you to set the following security properties:
   — Access permission: allow or deny access to users or groups to access this application.
   — Launch permission: allow or deny access to users or groups to run this application.
   — Configuration permission: identify users or groups who have read, write, or special access to the OpenVMS Registry area that contains information about the application.

3 - Identity: User account to use to run application
   This option allows you to run the application server using the security context of the specified user account.
   The system displays the Application Identity submenu.  See Section 6.3.4.

The system uses the systemwide default security values unless you specify a different setting.
The system displays the Application Security submenu.

**Figure 6–6 Application Security Submenu**

```

3 - Use Default Launch permission
4 - Edit Custom Launch permission
5 - Use Default Configuration permission
6 - Edit Custom Configuration permission

(E to Exit to previous menu)
(H for Help)
Please enter your choice:
```

The options are as follows:

- **1 - Use Default Access permission**
  Sets the system to the default access permission values.

- **2 - Edit Custom Access permission**
  Displays the Registry Value Permissions submenu. This submenu allows you to view, add, modify, and delete access permission values for this application. For this set of submenus, see Section 6.3.2.
  The ACL Editor starts with the systemwide default values unless you previously set other values.

- **3 - Use Default Launch permission**
  Use the systemwide default launch permission values.

- **4 - Edit Custom Launch permission**
  Displays the Registry Value Permissions submenu. This submenu allows you to view, add, modify, and delete launch permission values for this application. For this set of submenus, see Section 6.3.2.
  The ACL Editor starts with the systemwide default values unless you previously set other values.

- **5 - Use Default Configuration permission**
  Use the systemwide configuration permission values.

- **6 - Edit Custom Configuration permission**
  The system displays the Registry Key Permissions submenu. This submenu allows you to view, add, modify, delete, and configure special access security permissions for this application. For this set of submenus, see Section 6.3.3.
6.3.2 Registry Value Permissions Submenus

To display this submenu:

1. From the DCOM$CNFG menu, choose option 1.
2. From the Applications List submenu, choose any application.
3. From the Application Properties submenu, choose option 2.
4. From the Application Security submenu, choose option 2 or 4.

Name: OPENVMS_DCOM\USER1
Type of Access: Deny
1 - Delete entry from list
2 - Change Access
(E to Exit to previous menu)
(H for Help)
Please enter your choice:

The options are as follows:

• 1 - Delete entry from list
  Delete the entry from the Access Control List. If you delete all entries, you will deny access and launch permissions to everyone for the selected value.

• 2 - Change Access
  Toggle the access type from Allow to Deny or Deny to Allow.

Figure 6–9 Add Registry Value Permissions Submenu

Add Registry Value Permissions
Application name: Inside COM, Chapter 11 Example
Registry Value: LaunchPermission
Owner: ROLLO
1 - Add Specific User or Group
2 - Add Everyone
3 - Add NT AUTHORITY\System
4 - Add BUILTIN\Administrators
(E to Exit to previous menu)
(H for Help)
Please enter your choice:

The options are as follows:

— 1 - Add Specific User or Group
  Prompts for a user/group name and type of access. Specify the user name as domain\username or username if the account exists on the current domain.

— 2 - Add Everyone
  Allow or Deny Everyone Access/Launch permission to the application.

— 3 - Add NT AUTHORITY\System
  Allow or Deny System Access/Launch permission to the application.

— 4 - Add BUILTIN\Administrators
Allow or Deny Administrator Access/Launch permission to the application.

When a user is part of two or more groups, Deny access takes precedence over Allow access.

### 6.3.3 Registry Key Permissions Submenus

To display this submenu:

1. From the DCOM$CNFG menu, choose option 1.
2. From the Applications List submenu, choose any application.
3. From the Application Properties submenu, choose option 2.
4. From the Application Security submenu, choose option 6.

(E to Exit to previous menu)  
(H for Help)

Please enter your choice:

The options are as follows:

- **0 - Query Value**  
  Allow the user to read a value from the key.

- **1 - Set Value**  
  Allow the user to set one or more values for the key.

- **2 - Create Subkey**  
  Allow the user to create subkeys on the key.

- **3 - Enumerate Subkeys**  
  Allow the user to identify the subkeys of the key.

- **4 - Notify**  
  Allow the user to audit notification events from the key.

- **5 - Create Link**  
  Allow the user to create a symbolic link in the key.

- **6 - Delete**  
  Allow the user to delete the key.

- **7 - Write DACL**  
  Allow the user access to the key to write a discretionary ACL to the key.

- **8 - Write Owner**  
  Allow the user access to the key to take ownership of the key.

- **9 - Read Control**  
  Allow the user access to the key.
Allow the user access to the security information on the key.

**Figure 6–13  Add Registry Key Permissions Submenu**

Add Registry Key Permissions

Application name: Inside COM, Chapter 11 Example
Registry Key: Inside COM, Chapter 11 Example
Owner: Administrator

1 - Add Specific User or Group
2 - Add Everyone
3 - Add NT AUTHORITY\System
4 - Add BUILTIN\Administrators

(E to Exit to previous menu)
(H for Help)

Please enter your choice:

The options are as follows:

- **1 - Add Specific User or Group**
  Prompts for a user/group name and type of access. Specify the user name as domain\username or username if the account exists on the current domain.

- **2 - Add Everyone**
  Allow Everyone Full Control or Read Access to the application.

- **3 - Add NT AUTHORITY\System**
  Allow System Full Control or Read Access to the application.

- **4 - Add BUILTIN\Administrators**
  Allow Administrator Full Control or Read Access to the application.

**6.3.4 Application Identity Submenu**

To display this submenu:

1. From the DCOM$CNFG menu, choose option 1.
2. From the Applications List submenu, choose any application.
3. From the Application Properties submenu, choose option 3.

The system displays the Application Identity submenu.
The options are as follows:

- **1 - Launching User**
  Specifies that the application will run using the security context of the user who started the application. This is the default if NTLM security is available.

- **2 - NTLM Account**
  Specifies that the application will run using the security context of the specified NTLM account. If you specify a valid User/Group name, the system prompts you for a password. The system checks that the password matches the password you used to log on (through NTA$LOGON). If the passwords do not match, you can either continue and write this new password to the OpenVMS Registry or reenter a password that matches your logon password.

  Note
  If you enter a new password, the system does not synchronize the new password with any other password. You must synchronize the passwords manually.
  You must have the IMPERSONATE privilege for the password to be validated.
  You must have system write access (SYSPRV or REG$UPDATE) to the OpenVMS Registry to write the password to the database.

- **3 - OpenVMS Username**
  Specifies that the application will run using the security context of the specified OpenVMS account. This option is active only when you are using unauthenticated COM for OpenVMS.

- **4 - OpenVMS DCOM Guest Account**
  Specifies that the application will run using the security context of the OpenVMS DCOM Guest account. This option is active only when you are using unauthenticated COM for OpenVMS. If you are using unauthenticated COM for OpenVMS, this option is the default.
6.3.5 The DCOM$CNFG System-wide Default Properties Submenu

To display this submenu, from the DCOM$CNFG Main menu, choose option 2.
The system displays the System-wide Default Properties submenu.

**Figure 6–15 System-wide Default Properties Submenu**

```
System-wide Default Properties

(H for Help)
Please enter your choice:
```

The options are as follows:

- **1 - Enable Distributed COM on this computer (Yes/No)**
  Enables or disables COM on this computer.
- **2 - Default Authentication Level**
  Sets packet-level security on communications between applications. This systemwide default applies to all applications installed on this computer.

**Figure 6–16 Default Authentication Level Submenu**

```
Default Authentication Level
The Authentication Level specifies security at the packet level.
Current value: Connect
1 - Default
2 - None
3 - Connect
4 - Call
5 - Packet
6 - Packet Integrity

(E to Exit to previous menu)
(H for Help)
Please enter your choice:
```

Enter a number to select the desired Authentication level. When installed, the system default for the Default Authentication Level is Connect.

- **3 - Default Impersonation Level**
  Specifies whether applications can determine who is calling them, and whether the application can perform operations using the client's identity.
6.3 Running DCOM$CNFG

Figure 6–17 Default Impersonation Level Submenu

The Impersonation Level specifies whether applications can determine who is calling them, and whether the application can perform operations using the client’s identity.

Current value: Identify

1 - Anonymous
2 - Identify
3 - Impersonate

(E to Exit to previous menu)
(H for Help)

Please enter your choice:

Enter a number to select the desired Impersonation level. When installed, the system default for the Default Impersonation Level is Identify.

6.3.6 System-wide Default Security Submenu

To display this submenu, from the DCOM$CNFG Main Menu, choose option 3. The system displays the System-wide Default Security submenu.

Figure 6–18 System-wide Default Security Submenu

The options are as follows:

• 1 - Access Permissions Default:
  Displays the Registry Value Permissions submenu. This submenu allows you to view, add, modify, and delete Access permission values for the systemwide default for all applications.

• 2 - Launch Permissions Default:
  Displays the Registry Value Permissions submenu. This submenu allows you to view, add, modify, and delete Launch Permission Values for the systemwide default for all applications. You must restart the COM for OpenVMS Service Control Manager for the new setting to take effect.

• 3 - Configuration Permissions Default:
  Displays the security permission values for the HKEY_CLASSES_ROOT Registry key.
When you first install the system, by default only Administrator and System accounts have application launch and access permissions. Compaq recommends that you do not change these default settings. Typically you modify an individual application's launch and access security to grant or deny permissions to Everyone, various Groups, or even specific users. Compaq recommends this technique over adjusting the machinewide default security settings that affect all applications.

### 6.4 Registering In-Process Servers: DCOM$REGSVR32 Utility

All COM components (implemented as either an out-of-process server or as an in-process server) must be registered in the OpenVMS Registry before you can use them.

Out-of-process servers, which are implemented as executable programs (.EXE files), usually contain code to register and unregister the components contained within them. The advantage an out-of-process server has over an in-process server is that you can run the executable and automatically create the necessary registry keys.

In-process servers, which are usually implemented as dynamic link libraries (.DLL files) on Windows NT or as shareable images on OpenVMS, also contain code to register and unregister the components within them automatically. However, these in-process servers cannot be run the same way as an executable image because they do not contain a main entry point. As a result, you must manually register the components contained within a .DLL, or create a command procedure to perform the registration.

Microsoft provides the REGSVR32 utility that you can use to register the components contained within a DLL. REGSVR32 takes as a command line argument the following:

- DLL name
- Switches to register or unregister the components

When registering a DLL's components, REGSVR32 searches the specified DLL for the \texttt{DllRegisterServer} symbol and, if found, calls it. When unregistering a DLL, REGSVR32 calls \texttt{DllUnregisterServer}. This means that all in-process components that you want to register automatically must include these two entry points in their export files.

To facilitate the registration of components contained within shareable images on OpenVMS systems, Compaq created the DCOM$REGSVR32 utility. The DCOM$REGSVR32 utility does the same things that the Microsoft REGSVR32 utility does. Any shareable images that contain components to be registered must also include the \texttt{DllRegisterServer} and \texttt{DllUnregisterServer} universal symbols in their symbol vectors. Both the DCOM$REGSVR32 and the REGSVR32 utilities use the same command line syntax.

During the COM for OpenVMS installation, the system places the DCOM$REGSVR32.EXE file in the SY$SYSTEM directory.

Before you use the DCOM$REGSVR32 utility, you must define a symbol that allows the utility to accept foreign command lines. For example:

\texttt{$ \text{regsvr32} \ := \ $\text{DCOM}\$\text{REGSVR32}$}

Alternatively, you can activate the DCOM$REGSVR32 utility as follows:

\texttt{$ \text{MCR} \ \text{DCOM}\$\text{REGSVR32}$}
You can use either method to activate the utility, and register or unregister components contained in shareable images.

To display help for DCOM$REGSVR32, enter the following:

```
$ regsvr32 -?
```

Table 6–1 summarizes the DCOM$REGSVR32 command line options.

<table>
<thead>
<tr>
<th>Switch</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>-?, /?</td>
<td>Display help file (this table).</td>
</tr>
<tr>
<td>shareable-image-name</td>
<td>Register the specified shareable image name.</td>
</tr>
<tr>
<td>-u or /u image-name</td>
<td>Unregister the specified shareable image name.</td>
</tr>
</tbody>
</table>

**Note**

The DCOM$REGSVR32 utility requires that the shareable image name contain a full directory specification.

Example 6–4 demonstrates how to register an in-process component (contained within a shareable image) using the DCOM$REGSVR32 utility.

**Example 6–4  Registering a Component Using the DCOM$REGSVR32 Utility**

```
$ regsvr32 USER$DISK:[SEYMOUR.DISPATCH_SAMPLE1]CMPNT$SHR.EXE
Class factory: Create self.
DllRegisterServer: Registering Server DLL
Creating key CLSID\{0C092C2C-882C-11CF-A6BB-0080C7B2D682}\InProcServer32
Creating key CLSID\{0C092C2C-882C-11CF-A6BB-0080C7B2D682\}InProcServer32
Creating key CSP\{0C092C2C-882C-11CF-A6BB-0080C7B2D682\}\VersionIndependentProgID
Creating key CLSID\{0C092C2C-882C-11CF-A6BB-0080C7B2D682\}\TypeLib
Creating key InsideCOM.Chap11
Creating key InsideCOM.Chap11\CLSID
Creating key InsideCOM.Chap11\CurVer
Creating key InsideCOM.Chap11\CurVer\CLSID
Creating key Class factory: Destroy self.
```

Example 6–5 demonstrates how to unregister an in-process component (contained within a shareable image) using the DCOM$REGSVR32 utility.

```
$ regsvr32 -u USER$DISK:[SEYMOUR.DISPATCH_SAMPLE1]CMPNT$SHR.EXE
```

**Example 6–5 Regsitering a Component Using the DCOM$REGSVR32 Utility**

```
Class factory: Destroy self.
```
Example 6–5  Unregistering a Component Using the DCOM$REGSVR32 Utility

$ regsvr32 /u USER$DISK:[SEYMOUR DISPATCH SAMPLE1]CMPNT$SHR.EXE

Class factory: Create self.
DllUnregisterServer: Unregistering Server DLL
Deleting key InProcServer32
Deleting key ProgID
Deleting key VersionIndependentProgID
Deleting key TypeLib
Deleting key LocalServer32
Deleting key CLSID\{0C092C2C-882C-11CF-A6BB-0080C7B2D682\}
Deleting key CLSID
Deleting key CurVer
Deleting key InsideCOM.Chap11
Deleting key CLSID
Deleting key InsideCOM.Chap11.1
Class factory: Destroy self.
7

Developing a COM for OpenVMS Application

This chapter explains how to develop COM applications for OpenVMS.

Note
You can find the sample COM applications shown in this chapter in the following directories on the COM for OpenVMS kit:

DCOM$EXAMPLES:[SAMPLE1]
DCOM$EXAMPLES:[SIMPLE]
DCOM$EXAMPLES:[DISPATCH_SAMPLE1]

SAMPLE1 and DISPATCH_SAMPLE1 are taken from Dale Rogerson's book, Inside COM, published by Microsoft Press. This book is a good reference for developing COM applications.

The following sections describe how to create a COM for OpenVMS application.

Note
Building COM for OpenVMS applications places demands on the virtual memory requirements of a process. You should have a minimum page file quota of 100,000 pagelets before building a COM for OpenVMS application. This is a DEC C++ compiler requirement.

7.1 Step 1: Generate Unique Identifiers

Use the DCOM$GUIDGEN utility to generate 16-byte globally unique identifiers (GUIDs). The utility supports both OpenVMS and UNIX styles. For example:

• OpenVMS style
  Enter the following commands:

  $ SET COMMAND DCOM$LIBRARY:DCOM$GUIDGEN.CLD
  $ DCOM$GUIDGEN [/FORMAT=value] [/COUNT=value] [/OUTPUT=value]

• UNIX style
  Enter the following command:

  $ mcr dcom$guidgen [-cdghirs?] [-on]
Developing a COM for OpenVMS Application

7.1 Step 1: Generate Unique Identifiers

The following table summarizes the GUID format options.

<table>
<thead>
<tr>
<th>OpenVMS qualifier (value)</th>
<th>UNIX switch</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDL</td>
<td>-i</td>
<td>Output GUID in an IDL interface template.</td>
</tr>
<tr>
<td>STRUCT</td>
<td>-s</td>
<td>Output GUID as an initialized C struct.</td>
</tr>
<tr>
<td>IMPLEMENT_OLECREATE</td>
<td>-c</td>
<td>Output GUID in IMPLEMENT_OLECREATE(...) format.</td>
</tr>
<tr>
<td>DEFINE_GUID</td>
<td>-d</td>
<td>Output GUID in DEFINE_GUID(...) format.</td>
</tr>
<tr>
<td>GUID_STRUCT</td>
<td>-g</td>
<td>Output GUID as an initialized static const GUID struct.</td>
</tr>
<tr>
<td>REGISTRY_GUID</td>
<td>-r</td>
<td>Output GUID in registry format.</td>
</tr>
</tbody>
</table>

Note: The last four options in the preceding table are the same as the four options in the Windows NT Guidgen utility.

The following table lists additional options supported by the DCOM$GUIDGEN utility.

<table>
<thead>
<tr>
<th>OpenVMS qualifier</th>
<th>UNIX switch</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>/OUTPUT=filename</td>
<td>-o filename</td>
<td>Redirect output to a specified file.</td>
</tr>
<tr>
<td>/COUNT=number</td>
<td>-n number</td>
<td>Number of GUIDs to generate.</td>
</tr>
<tr>
<td>not available</td>
<td>-h, -?</td>
<td>Display command option summary.</td>
</tr>
</tbody>
</table>

You can specify more than one format for the same GUID.

7.2 Step 2: Build an Application Using the MIDL Compiler

The following sections describe how to use the MIDL compiler to build an application.

7.2.1 Running the MIDL Compiler

The MIDL compiler consists of the following separate images:

- SYS$SYSTEM:DCOM$MIDL.EXE
  The executable image that takes its arguments (parameters) from the DCL command line.

- SYS$SHARE:DCOM$MIDL_SHR.EXE
  A shareable image library that does the actual work for DCOM$MIDL.EXE.

To run MIDL, you must first define a DCL symbol. For example:

```
$ midl := $dcom$midl
$ midl -?
$ midl -Oicf -idcom$library: example.idl
```

The midl -? command displays a list of valid command line arguments. For a list of these arguments, see Appendix A.
7.2.2 Running the MIDL Compiler with DCOM$RUNSHRLIB

The DCOM$MIDL.EXE utility gets its arguments from the DCL foreign command line buffer. DCL foreign commands can have a maximum of 255 characters.

Because of the number of arguments that DCOM$MIDL.EXE can accept, you might exceed this maximum number of characters if you specify a complex MIDL command (for example, a command that contains mixed-case arguments that require quotation marks).

As a workaround, you can use the SYS$SYSTEM:DCOM$RUNSHRLIB.EXE utility. Use the following procedure:

1. Define the DCL command DCOM$RUNSHRLIB.

A process that needs to use DCOM$RUNSHRLIB.EXE must first use the OpenVMS DCL Command Definition utility to define the DCL command DCOM$RUNSHRLIB. For example:

```$SET COMMAND DCOM$LIBRARY:DCOM$RUNSHRLIB.CLD
DCOM$LIBRARY:DCOM$RUNSHRLIB.CLD defines the DCOM$RUNSHRLIB DCL command. The following table shows the command's parameters.
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
<th>Required/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>Name of the shareable image library. This can be a logical name, the name of an image in SYS$SHARE:, or a full file specification.</td>
<td>Required</td>
</tr>
<tr>
<td>P2</td>
<td>Name of the routine to be called as a C or C++ main() routine with an argc/argv vector.</td>
<td>Required</td>
</tr>
<tr>
<td>P3</td>
<td>List of qualifiers in quotation marks.</td>
<td>Optional</td>
</tr>
</tbody>
</table>

2. Define the DCL symbol midl to use DCOM$RUNSHRLIB.EXE to parse the command line and call the DCOM$MIDL_MAIN function in the DCOM$MIDL_SHR shareable image library. For example:

```$midl := DCOM$RUNSHRLIB DCOM$MIDL_SHR DCOM$MIDL_MAIN
The new DCL command MIDL accepts multiple command line arguments inside a single quoted string. If the command becomes too long, you can specify multiple quoted strings, using a comma to separate the strings.
```

For example, here is a complex MIDL command that fails:

```$midl := $dcom$midl
$midl -Zp8 -Oicf -Os -oldnames -char unsigned -
    -error allocation -error bounds_check -error stub_data -
    -ms_ext -c_ext -out [.OBJ] -
    -I[INC] -I[PROJECT_WIDE_INC] -I[COMMON_INC] -IDCOM$LIBRARY: -
    -DRMS_DB "-DOpenVMS_Dependencies" "-DPermanentProcess" -
    -header [.obj]example.h -client none -server none example.idl
    %DCL-W-TKNOVF, command element is too long - shorten
You can successfully specify this command using DCOM$RUNSHRLIB as follows:
```
Developing a COM for OpenVMS Application

7.2 Step 2: Build an Application Using the MIDL Compiler

$ set command dcom$library:dcom$runshrlib.cld
$ midl :== DCOM$RUNSHRLIB DCOM$MIDL_SHR DCOM$MIDL_MAIN
$ midl "-Zp8 -Oicf -Os -oldnames -char unsigned",-
"-error allocation -error bounds_check -error stub_data",-
"-ms_ext -c_ext -out [.OBJ],-
"-DRMS_DB -DOpenVMS_Definitions -DPermanentProcess",-
"-header [.obj]example.h -client none -server none example.idl"

7.2.3 Required MIDL Switches

When running MIDL on OpenVMS, you must specify the -Oicf MIDL command line switch.

7.2.4 Required Include Directories

MIDL components typically import UNKNWN.IDL, which contains the component definitions for IUnknown and IClassFactory. UNKNWN.IDL and other COM-related IDL and header files are located in DCOM$LIBRARY. To build your component's IDL file, use the following switch:

-IDCOM$LIBRARY:

7.2.5 Required Header File

The VMS_DCOM.H header file contains macro definitions that enable your COM for OpenVMS application to compile properly with Bristol's Wind/U® Win32 environment. You must include this header file in every source file and header file you create that relies on COM APIs or Win32 APIs. Because the files generated by MIDL rely on parts of the Win32 environment, Compaq has modified the MIDL compiler for OpenVMS to include VMS_DCOM.H in all output files.

7.3 Step 3: Compile the COM Application

The following sections describe how to compile COM for OpenVMS applications.

Note

A COM application developer will need access to the OpenVMS registry to register and control access to a given application. For more information about OpenVMS Registry privileges, see Section 10.5.1 and Section 6.3.

7.3.1 Required Macro Definitions

The VMS_DCOM.H file defines several macros used by the Wind/U Win32 environment. An include statement that specifies this header file should be the first noncommented line in any source file (code or header files) that you write. However, this is not always guaranteed to be true for files generated by MIDL. Be sure to always include the following /DEFINE qualifier on all of your C and CXX commands:

/DEFINE=(UNICODE=1,_WINDU_SOURCE=0X041000,_WIN32_DCOM)

The UNICODE macro ensures that the wide character variants of Win32 APIs and data structures are enabled when you compile your code. (This macro is also defined in VMS_DCOM.H.) Omitting this macro can lead to compilation failures when building with the Wind/U Win32 environment.

The other two macro definitions are recognized by the Wind/U header files and are required to ensure the proper definition of structures and COM APIs.
7.3.2 Required Include Directories

COM for OpenVMS applications typically require header files that come from DCOM$LIBRARY.

Include the following qualifier on your C and CXX command lines:

\[ /\text{INCLUDE}=\text{DCOM$LIBRARY} \]

If you already have an /INCLUDE qualifier on your command line, modify the command to include DCOM$LIBRARY.

7.3.3 Required Header File: VMS_DCOM.H

The VMS_DCOM.H header file defines several macros used by the Wind/U header files.

Include this header file as the first noncommented line in your source files (both header files and implementation files).

7.3.4 Required C++ Qualifiers

You must specify the following C++ qualifiers when you build COM for OpenVMS applications:

- /EXCEPTIONS=CLEANUP
  Specify the /EXCEPTIONS=CLEANUP qualifier on C++ commands to enable C++ exceptions.
- /STANDARD=CFRONT
  The C++ compiler supports many different compilation standards. Compaq recommends that you use /STANDARD=CFRONT.

/STANDARD=CFRONT informs the compiler that it should follow the language conventions defined in the AT&T® cfront implementation. This switch works well with the Wind/U header files because those header files are used by several UNIX platforms in addition to the OpenVMS platform.

7.3.5 Required C Qualifiers

There are no qualifiers unique to DEC C that you must specify when you build COM for OpenVMS applications.

7.4 Step 4: Link the COM Application

To build a COM for OpenVMS application, you must build both client and component images. Because you can implement a component as either an in-process component or an out-of-process component, you must build either a shareable image or an executable image, or both. If you are creating a new interface, you must also build a proxy/stub shareable image, unless you are using the IDispatch interface. In that case, the Automation Marshaler will be used instead of the proxy/stub shareable image. The proxy/stub shareable image provides an interface-specific object that packages parameters for that interface in preparation for a remote method call. A proxy runs in the sender’s address space and communicates with a corresponding stub in the receiver’s address space.

The following sections describe the steps you must follow to link the client, component, and proxy/stub images.
7.4 Step 4: Link the COM Application

7.4.1 Linking the Client and the Out-of-Process Component

Although you do not need to specify any qualifiers to link the client or the component executable images, you must link both images with the following:

- The Wind/U shareable images (to satisfy Win32 dependencies)
- The DCOM OLE32 shareable image (to satisfy references to COM APIs)

The specific link-time dependencies are as follows:

- DCOM$WIN32:WINDU.OPT
- DCOM$LIBRARY:DCOM.OPT

If you have one or more C++ modules, use the C++ linker (CXXLINK) instead of the standard OpenVMS linker so you can specify the location of your C++ repository (/CXX_REPOSITORY qualifier). For example:

```
$ CXXLINK/your-specific-linker-qualifiers list-of-object-modules, -
_&$ DCOM$WIN32:WINDU.OPT/OPTIONS, DCOM$LIBRARY:DCOM.OPT/OPTIONS -
_&$ application.OPT/OPTIONS /REPOSITORY=[/CXX_REPOSITORY]
```

Other ways of including the options file are as follows:

- Include the list of object modules in an options file instead of on the command line.
- Use DCOM$LIBRARY:DCOM.OPT.

7.4.2 Linking the In-Process Component Shareable Image

The component in-process shareable image dependency list differs slightly from that of the client and component executables. The specific link-time dependencies are as follows:

- DCOM$WIN32:WINDU.OPT
- DCOM$LIBRARY:DCOM.OPT

7.4.2.1 Creating a Symbol Vector

Linking the in-process component shareable image requires that you create a symbol vector for the entry points that COM for OpenVMS expects to call within the shareable image. The Win32 run-time environment enforces a naming standard on the DllMain entry point, which must contain the following:

- _Windu_ prefix
- Actual entry point name
- A suffix that includes the image name or a portion of the image name, depending on the format of the image name.

If the image name ends in $SHR (for example, CMPNT$SHR), the suffix is the image name up to and including the dollar sign ($).

If the image name ends in anything other than $SHR (for example, CMPNT_SHARE), the suffix is the full image name.

For example, a component shareable image with the name CMPNT$SHR would define the symbol vector using the following options file:
7.4 Step 4: Link the COM Application

The list of symbols exported by CMPNT$SHR.EXE.

SYMBOL VECTOR=(-
    _WindU_DllMain_CMPNT$/DllMain = PROCEDURE,-
    DllGetClassObject = PROCEDURE,-
    DllCanUnloadNow = PROCEDURE,-
    DllRegisterServer = PROCEDURE,-
    DllUnregisterServer = PROCEDURE)

A component shareable image with the name CMPNT_SHARE would define the symbol vector using the following options file:

The list of symbols exported by CMPNT_SHARE.EXE.

SYMBOL VECTOR=(-
    _WindU_DllMain_CMPNT_SHARE/DllMain = PROCEDURE,-
    DllGetClassObject = PROCEDURE,-
    DllCanUnloadNow = PROCEDURE,-
    DllRegisterServer = PROCEDURE,-
    DllUnregisterServer = PROCEDURE)

7.4.3 Linking the Proxy/Stub Shareable Image

The proxy/stub shareable image dependency list differs slightly from that of the client and component executables. The specific link-time dependencies are as follows:

- DCOM$WIN32:WINDU.OPT
- SYSS$LIBRARY:DCOM$RPCRT4_SHR.EXE

7.4.3.1 Creating a Symbol Vector

Linking the proxy/stub shareable image is more involved because you must create a symbol vector for the entry points that COM for OpenVMS expects to call within the shareable image. The Win32 run-time environment enforces a naming standard on the DllMain entry point, which must contain the following:

- _Windu_ prefix
- Actual entry point name
- A suffix that includes the image name or a portion of the image name, depending on the format of the image name.
  - If the image name ends in $SHR (for example, PROXY$SHR), the suffix is the image name up to and including the dollar sign ($).
  - If the image name ends in anything other than $SHR (for example, PROXY_SHARE), the suffix is the full image name.

For example, a proxy/stub shareable image with the name PROXY$SHR would define the symbol vector using the following options file:
Developing a COM for OpenVMS Application

7.4 Step 4: Link the COM Application

```
! RPC Shareable Image
! SYS$LIBRARY:DCOM$RPCRT4_SHR.EXE/SHARE
!
! The list of symbols exported by PROXY$SHR.EXE.
!
SYMBOL_VECTOR=(-
   _Windu_DllMain_PROXY$/DllMain = PROCEDURE,-
   DllGetClassObject = PROCEDURE,-
   DllCanUnloadNow = PROCEDURE,-
   GetProxyDllInfo = PROCEDURE,-
   DllRegisterServer = PROCEDURE,-
   DllUnregisterServer = PROCEDURE)
```

A proxy/stub shareable image with the name PROXY_SHARE would define the symbol vector using the following options file:

```
! RPC Shareable Image
! SYS$LIBRARY:DCOM$RPCRT4_SHR.EXE/SHARE
!
! The list of symbols exported by PROXY_SHARE.EXE.
!
SYMBOL_VECTOR=(-
   _Windu_DllMain_PROXY_SHARE/DllMain = PROCEDURE,-
   DllGetClassObject = PROCEDURE,-
   DllCanUnloadNow = PROCEDURE,-
   GetProxyDllInfo = PROCEDURE,-
   DllRegisterServer = PROCEDURE,-
   DllUnregisterServer = PROCEDURE)
```

7.5 Required OpenVMS Registry Entries

The following sections list and describe the required OpenVMS Registry entries.

7.5.1 HKEY_CLASSES_ROOT\CLSID

The CLSID subkey contains all CLSIDs for the components supported on your system. You must register your components’ CLSIDs here. Each registered CLSID should contain the following:

- An unnamed value whose type is a zero-terminated string with a data value describing the component.
- A named value, AppID, whose type is a zero-terminated string with a data value that is the CLSID of the component.

7.5.1.1 Component CLSIDs

A class identifier (CLSID) is a globally unique identifier (GUID) associated with an OLE class object. COM for OpenVMS server applications typically register their CLSIDs in the OpenVMS Registry so clients can locate and load the executable code associated with the OLE class object.

Register the CLSID for the component under the subkey HKEY_CLASSES_ROOT\CLSID.

A component CLSID registration should contain the following subkeys:

- LocalServer32
This key's value should contain a zero-terminated string with a data value that is the location of the out-of-process server executable.

- **ProgID**
  This key's value should contain a zero-terminated string with a data value that is the programmatic ID of the CLSID. These are typically of the format program.component.version.

- **VersionIndependentProgID**
  This key's value should contain a zero-terminated string with a data value that is the programmatic ID (less the version number) of the CLSID. These are typically of the format program.component.

- **InProcServer32**
  This key's value should contain a zero-terminated string with a data value that is the location of the in-process server's shareable image.

- **Type Libraries**
  Type libraries are important for implementing the IDispatch interface. A type library registers itself when it calls the OLE Automation RegisterTypeLib run-time routine. You must also add a Typelib subkey under your component's CLSID. The Typelib subkey contains your type library's GUID. For example, the following key should contain your LIBID:

  HKEY_CLASSES_ROOT\CLSID\{GUID}\TYPELIB (value=LIBID)

### 7.5.2 HKEY_CLASSES_ROOT\Interface

The Interface subkey contains all interfaces registered with the system. You must register the component's interface IDs (IIDs) in this subkey.

Each interface registered contains at least one of the following subkeys:

- **NumMethods**
  The NumMethods value should contain a zero-terminated string with a data value that is the number of methods contained in the interface.

- **ProxyStubClsid32**
  The ProxyStubClsid32 value should contain a zero-terminated string with a data value that is the location of the proxy/stub shareable image. The proxy/stub CLSID and its subkey enable COM to locate the proxy/stub shareable image.
Developing a COM for OpenVMS Application

7.5 Required OpenVMS Registry Entries

The ProxyStubClsid32 value should contain a zero-terminated string with a data value that is the CLSID of the proxy/stub shareable image. This CLSID should be the same as that described in Section 7.5.1.2.

7.6 Converting OpenVMS and Windows Error Codes to Text

As you develop and test COM components, you will find that the OpenVMS and Windows NT systems return seemingly indecipherable error codes. To help you make these codes more understandable, Compaq has included the NTA$VMSGetMessage routine to translate error codes into displayable text.

To implement this routine, you must include the NTA_MESSAGE.H file in the DCOM$LIBRARY: directory and link with the DCOM$LIBRARY:NTA_GETMSG.OBJ object module.

The following section describes the NTA$VMSGetMessage routine.
The NTA$VMSGetMessage routine translates error codes into displayable text. The input error code must be one of the following:

- An OpenVMS error code
- A Windows HRESULT
- A Windows Win32 error code
- A Windows NT status code set as “user defined”

**Format**

```
Return=NTA$VMSGetMessage (status, text, flag, [count])
```

**Arguments**

**status**

OpenVMS usage: error_code  
type: longword (unsigned)  
access: read only  
mechanism: by value

This status field must be one of the following:

<table>
<thead>
<tr>
<th>Input Error Code</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenVMS error code</td>
<td>0x074AA6BA</td>
</tr>
<tr>
<td>Windows HRESULT</td>
<td>0x80070031</td>
</tr>
<tr>
<td>Windows Win32 error code</td>
<td>0x00000031</td>
</tr>
<tr>
<td>Windows NT status code with the user-defined bit set</td>
<td>0xE74AA6BA</td>
</tr>
</tbody>
</table>

If the security API returns a Windows NT status code, the format of the status field is an OpenVMS status code OR’d with the Windows NT status control bits set. For example:

<table>
<thead>
<tr>
<th>Input Error Code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenVMS error code</td>
<td>0x074AA6BA</td>
</tr>
<tr>
<td>Windows NT status code</td>
<td>0xE74AA6BA</td>
</tr>
</tbody>
</table>

**text**

OpenVMS usage: error_text  
type: character string  
access: write  
mechanism: by reference

This argument is a NULL terminated string that contains the returned text from the SYS$GETMSG system service. The maximum size returned (as defined by the SYS$GETMSG system service) is 256 bytes. To avoid overwriting memory, the caller must provide a buffer address of at least 257 bytes.
Developing a COM for OpenVMS Application

NTA$VMSGetMessage

flag
OpenVMS usage: flag
type: longword (unsigned)
access: read only
mechanism: by value

Controls the translation of the error code. The following values are defined in NTA_MESSAGE.H:

- NTAWIN$_UNKNOWN Unknown error code
- NTAWIN$_VMS OpenVMS error code
- NTAWIN$_NT Windows HRESULT error code
- NTAWIN$_WINDOWS Windows Win32 error code
- NTAWIN$_USER Windows NT status code

If you provide the value NTAWIN$_UNKNOWN, the routine makes its best estimate as to the correct text. The routine parses the text as follows:

1. Check for a Windows HRESULT (high-order nibble = 0x8). If this check fails, go to the next step.
2. Check for a Windows NT user defined status code (high-order nibble = 0xE). If this check fails, go to the next step.
3. Assume this is an OpenVMS error code.

The system cannot tell the difference between an OpenVMS error code and a Windows Win32 error code.

count
OpenVMS usage: FAO count
type: longword (unsigned)
access: write
mechanism: by reference

This argument is the optionally returned FAO argument count in the returned message. Currently all NTAWIN messages use ASCII substitution arguments (IAS) only. The caller must convert all numeric data to ASCII before performing the substitution with SYS$FAO.

Description

This routine uses the OpenVMS SYS$GETMSG system service. The messages are stored in the SYS$MESSAGE:NTAWINMSG.EXE and SYS$MESSAGE:NTARPCMSG.EXE images.

To call this routine, you must include the NTA_MESSAGE.H file in the DCOM$LIBRARY: directory and link with the SYS$LIBRARY:DCOM$WIN32_SHR shareable image.

Condition Values Returned

Any status from the SYS$GETMSG system service.

For more information about the SYS$GETMSG system service, see the OpenVMS System Services Reference Manual.
8 Authentication

8.1 What is Authentication?

Authentication is the act of verifying a user’s identity by the computer system before permitting access to the system. After successfully authenticating a user, the system binds the user’s authorization information to the user’s process in the form of credentials. The system uses these credentials to determine whether to grant or deny access to system resources.

OpenVMS provides both native (SYSUAF-based) and Windows NT-compatible authentication and authorization capabilities as follows:

- **Native**: The system performs authentication using password information stored in the SYSUAF.DAT file. Authorization information consists of UIC, privileges, and rights identifiers.

- **Windows NT**: The system performs authentication using password information stored in a SAM database managed by domain controllers. Authorization information consists of primary SID, group SIDs, session key, and privileges obtained from the user’s account information in the SAM database.

After OpenVMS successfully authenticates a user (either native or Windows NT), OpenVMS attaches the user’s native credentials to the process using a structure known as a persona. If the system used Windows NT for authentication, OpenVMS also attaches the user’s Windows NT credentials to the process (as an extension to the persona).

8.2 Acquiring Windows NT Credentials Using NTA$LOGON

NTA$LOGON is a utility that allows you to acquire NTLM credentials. All processes that need Windows NT security to access the OpenVMS Registry or COM for OpenVMS facilities require NTLM credentials.

You must provide NTA$LOGON with a user account name, a password, and (if required) a domain name. NTA$LOGON uses the Authentication and Credential Management (ACM) Authority to contact the domain controller and acquire a Windows NT access token. NTA$LOGON merges the Windows NT information with the user’s OpenVMS credentials.

For a detailed review of NTA$LOGON dependencies and a description of how NTA$LOGON interacts with other parts of the OpenVMS infrastructure, see Section 5.1 and Section 4.8 (especially the ACME server and Advanced Server for OpenVMS server).

To use the NTA$LOGON utility, you can enter any of the following:

- Enter the following command to run the NTA$LOGON utility:

  \$ RUN SYSSYSTEM:NTA$LOGON
The system prompts you for a user account name and password.

- Define a DCL symbol to use NTA$LOGON to parse the command line. For example:

  $ NTLOGON ::= $NTA$LOGON
  $ NTLOGON

  You can specify parameters on the command line. Table 8–1 shows the command line parameters. If you do not specify any parameters, the system prompts you for the required information.

- Use the MCR command to use NTA$LOGON to parse the command line. For example:

  $ MCR NTASTLOGON

  You can specify parameters on the command line. Table 8–1 shows the command line parameters. If you do not specify any parameters, the system prompts you for the required information.

Table 8–1 shows the NTA$LOGON utility command line parameters.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
<th>Required/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>User account name. If an account name is needed but was not specified on the command line, NTA$LOGON prompts for input.</td>
<td>Optional</td>
</tr>
<tr>
<td>P2</td>
<td>Password. If a password is needed but was not supplied on the command line, NTA$LOGON prompts for input (echoing suppressed).</td>
<td>Optional</td>
</tr>
</tbody>
</table>

Example 8–1 shows a typical NTA$LOGON session to acquire credentials.

**Example 8–1 Sample NTA$LOGON Session**

  $ NTLOGON ::= $NTA$LOGON
  $ NTLOGON joesmith
  Password:

  Note

  Windows NT domain names and user account names are not case sensitive. NTA$LOGON converts all domain names and user account names to uppercase. If you specify a password on the command line, DCL converts all characters to uppercase, unless you enclose the password in quotation marks ("").
8.2 Acquiring Windows NT Credentials Using NTA$LOGON

8.2.1 NTA$LOGON Optional Qualifiers

NTA$LOGON accepts the following optional qualifiers:

- /DELETE
  Deletes the current Windows NT credentials.
  If you specify the /DELETE qualifier with the /WRITE_FILE qualifier, the system deletes the password record for the specified domain name and user account name from the file.

- /DOMAIN=<name>
  Specifies a domain name. This qualifier converts the name to uppercase. If you do not specify this qualifier, the system uses the default domain name.

- /LIST
  Lists the domain name and the user account name assigned to the current process.
  If you use the /LIST qualifier with the /READ_FILE or /WRITE_FILE qualifier, the system lists the contents of the file.

- /LOG
  Displays a message when an operation completes.

- /OVERRIDE_MAPPING
  Acquires Windows NT credentials for the specified Windows NT user account name even if the OpenVMS user name of the process does not match the OpenVMS user name associated with that Windows NT user account name in the domain controller.
  This qualifier requires the IMPERSONATE privilege.

- /READ_FILE [=file]
  This qualifier causes the system to search the binary input file created by the /WRITE_FILE qualifier for the specified domain name and user account name, instead of reading the password from the user input device. The /READ_FILE qualifier supports only binary files created by the NTA$LOGON/WRITE_FILE command.
  If the system finds a matching record, NTA$LOGON attempts to use that password to acquire Windows NT credentials.
  If you do not provide a file specification, the system uses the following default file specification:

  \DCECOMMON\[000000]\NTA$LOGON.DAT

- /TYPE={BATCH | DIALUP | LOCAL | NETWORK | REMOTE}
  Specifies the rules under which access is to be granted or denied. If you do not specify this qualifier, the default is the type of the current process. This qualifier is usually used for detached processes (detached processes do not have a default type).
  This qualifier requires IMPERSONATE privilege.

- /WRITE_FILE [=file]
  This qualifier causes the system to write the specified domain name, user account name, and password into an output file to be used later (see the /READ_FILE qualifier), instead of using the user-supplied password.
8.2 Acquiring Windows NT Credentials Using NTA$LOGON

If you do not provide a file specification, the system uses the following default location and file name:

DCE$COMMON:[000000]NTA$LOGON.DAT

--- Caution ---

The /READ_FILE and /WRITE_FILE qualifiers are intended to be used only by servers that have no other way to acquire Windows NT credentials to access the OpenVMS Registry or COM for OpenVMS facilities. Compaq does not recommend general use of the /READ_FILE and /WRITE_FILE qualifiers.

Once you have written a password into a disk file, Compaq recommends you take strong precautions to protect the password file from unauthorized access.

8.2.2 Examples of Using NTA$LOGON to Acquire Windows NT Credentials

Example 8–2 shows how a user acquires NT credentials for the first time.

**Example 8–2  Acquiring Windows NT Credentials for the First Time**

```bash
$ NTLOGON ::= $NTA$LOGON
$ NTLOGON/LIST
ERROR: NtOpenProcessToken() failure: -1073741700 0xc000007c
%SLECT-E-NOSUCHLEX, no such extension found

$ NTLOGON/LOG JOESMITH
[Persona #1 NT extension: Account= "JOESMITH" Domain= "NT_DOMAIN" ]
Password:
```

Example 8–3 shows how the user replaces the Windows NT credentials.

**Example 8–3  Replacing Windows NT Credentials**

```bash
$ NTLOGON/DELETE
$ NTLOGON/OVERRIDE_MAPPING/DOMAIN=OTHER_DOMAIN
Username: janebrown
Password:
```

Example 8–4 shows how a user saves a password in a disk file. The system requests that the user enter the password twice with echoing suppressed.

**Example 8–4  Saving a Password to a File**

```bash
$ NTLOGON ::= $NTA$LOGON
$ NTLOGON/WRITE_FILE=DEV:[DIR]NTA$LOGON.DAT COM_SERVER
Password:
Confirm:
$ NTLOGON/READ_FILE=DEV:[DIR]NTA$LOGON.DAT/LIST
File DEV:[DIR]NTA$LOGON.DAT contains the following records:
02-MAR-1999 16:57:23.20 COM_SERVER
```
8.2 Acquiring Windows NT Credentials Using NTA$LOGON

After you have created this file, you can add the following to a DCL command procedure:

```c
$ NTLOGON ::= $NTA$LOGON
$ NTLOGON/READ_FILE=DEV:[DIR]NTA$LOGON.DAT COM_SERVER
```

8.3 The Authentication and Credential Management (ACM) Authority

The Authentication and Credential Management authority authenticates users and determines the user security profile for OpenVMS and Windows NT. The ACME_SERVER process provides these ACM services. The ACME_SERVER process uses plug-in modules called ACME agents. ACME agents perform the actual work of responding to authentication requests, query requests, and event requests.

The OpenVMS ACME agent (VMS$VMS_ACMESH.REX) provides OpenVMS native services. The MSV1_0 ACME agent (PWRK$MSV1_0_ACMESH.REX, an Advanced Server for OpenVMS product component) provides Windows NT connectivity services.

The MSV1_0 ACME agent forwards Windows NT connectivity service requests from NTA$LOGON and SSPI/NTLM to an Advanced Server for OpenVMS process running on one or more systems in the cluster. The PWRK$ACME_SERVER logical name can contain a comma-delimited list of cluster node names to which the MSV1_0 ACME can forward requests. Running the Advanced Server for OpenVMS process on more than one cluster node and including the node names in the PWRK$ACME_SERVER logical name allows the MSV1_0 ACME agent to fail over a request automatically if a connection is interrupted. If the logical name is undefined, the system defaults to the local machine name.

The ACME_SERVER process must be present on any system running RPC or COM for OpenVMS. However, the Advanced Server for OpenVMS process needs to be present on only one node in the cluster.

8.3.1 Windows NT Authentication on OpenVMS

Because the ACME_SERVER returns to its callers a complete OpenVMS persona with the requested attached Windows NT persona extension, the VMS ACME agent enforces the following rules:

- Every Windows NT user must be mapped to a local OpenVMS user name. The MSV1_0 ACME provides this mapping through the Advanced Server for OpenVMS HOSTMAP database.
- The mapped OpenVMS user name must be a valid (and not disabled) account in the SYSUAF.DAT. The account's access restrictions must allow access during the specified days and times. COM for OpenVMS and RPC typically require NETWORK access during authentication.
- The mapped OpenVMS user name must be an account with the EXTAUTH flag set. EXTAUTH allows the system manager fine control over which OpenVMS accounts can be used for mapping. You can use the IGNORE_ExtAuth bit (bit number 11 [decimal]) in the SECURITY_POLICY system parameter to override this per-account feature. If you set the IGNORE_ExtAuth bit to 1, OpenVMS allows you to map to any account, regardless of the account's EXTAUTH setting. Note that the IGNORE_EXTAUTH is used only for the ACME_SERVER and is ignored by Loginout.
8.3 The Authentication and Credential Management (ACM) Authority

8.3.2 Managing the ACME_SERVER Process (ACME Server Commands)

To start the ACME_SERVER process and configure the MSV1_0 ACME agent at system startup, add the following entry to SYLOGICALS.COM:

```
$ DEFINE NTA$NT_ACME_TO_BE_STARTED YES
```

You can also start the ACME_SERVER process manually using the following startup command file:

```
$ @SYS$STARTUP:NTA$STARTUP_NT_ACME
```

To shut down ACME_SERVER, enter the following command:

```
$ SET SERVER ACME/EXIT
```

If an abnormal condition in an ACME agent prevents a normal server shutdown, use the /ABORT qualifier in the place of the /EXIT qualifier to force the ACME_SERVER to terminate.

To turn on ACME_SERVER logging, enter the following command:

```
$ SET SERVER ACME/LOG
```

This command creates a ACME$SERVER.LOG file in the SYS$MANAGER directory. You might find this file useful when you are trying to diagnose potential problems.

To display the ACME_SERVER configuration information, enter the following command:

```
$ SHOW SERVER ACME[/FULL]
```

8.3.3 Configuring the MSV1_0 ACME Agent

Table 8–2 lists and describes systemwide logical names you can use to control certain features of the MSV1_0 ACME agent.

<table>
<thead>
<tr>
<th>Logical name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PWRK$ACME_SERVER</td>
<td>Comma-delimited list of cluster SCS node names that are running Advanced Server for OpenVMS processes that can service Windows NT connectivity requests. If you do not define the node names, the MSV1_0 ACME agent tries to connect to the Advanced Server for OpenVMS process on the local system.</td>
</tr>
<tr>
<td>PWRK$ACME_RETRY_COUNT</td>
<td>The maximum number of retry attempts the MSV1_0 ACME agent performs when connecting to an Advanced Server for OpenVMS process. The default value is 10.</td>
</tr>
<tr>
<td>PWRK$ACME_RETRY_INTERVAL</td>
<td>The number of tenths of seconds between retry attempts. The default is 2.5 seconds.</td>
</tr>
</tbody>
</table>
9.1 COM for OpenVMS and ATL

ATL (Active Template Library) is a set of template-based C++ classes from Microsoft that simplify the development of COM components. ATL provides support for key COM features, such as stock implementations of IUnknown, IClassFactory, IDispatch, dual interfaces, and connection points. It also provides support for more advanced COM features, such as enumerator classes and tear-off interfaces.

The ATL COM AppWizard and ATL Object Wizard in Microsoft Visual Studio can be used to quickly create code for simple COM objects that can be copied to OpenVMS systems and built with very few modifications.

The COM for OpenVMS ATL is based on Microsoft ATL Version 3.0. You must be running COM Version 1.1-B for OpenVMS or higher. ATL on OpenVMS Alpha Version 7.2-1 requires Compaq C++ Version 6.2-016 or higher.

COM for OpenVMS provides ATL as source code in header files that you include in your application.

Table 9–1 shows the differences between the ATL implementation on Windows NT and OpenVMS.

<table>
<thead>
<tr>
<th>Implementation</th>
<th>Windows NT</th>
<th>OpenVMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>

9.2 Developing a COM for OpenVMS Application Using ATL

The following sections describe how to create a COM for OpenVMS application using ATL.
## 9.2 Developing a COM for OpenVMS Application Using ATL

### 9.2.1 Step 1: Create the ATL Component in Microsoft Visual Studio

Generate the code using the Microsoft Visual Studio ATL COM AppWizard. For information about using the ATL COM AppWizard, see the Microsoft Developer Network (MSDN) documentation.

Copy the generated files to OpenVMS. For example, copy the files using File Transfer Protocol (FTP) in ASCII mode. Table 9–2 lists and describes the files that the ATL COM AppWizard would generate for a project named `mycomapp`.

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
<th>Platform</th>
<th>In-Process or Out-of-Process</th>
</tr>
</thead>
<tbody>
<tr>
<td>mycomapp.cpp</td>
<td>Contains the implementation of DllMain, DllCanUnloadNow, DllGetClassObject, DllRegisterServer and DllUnregisterServer. Also contains the object map, which is a list of the ATL objects in your mycomapp. This is initially blank, because you have not created an object yet.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>mycomapp.def</td>
<td>The standard Windows module definition file for the DLL. <strong>Note:</strong> MYCOMAPP.DEF becomes MYCOMPAPP$SHR.OPT on OpenVMS.</td>
<td>Windows NT</td>
<td>In-process</td>
</tr>
<tr>
<td>mycomapp.dsw</td>
<td>The mycomapp workspace.</td>
<td>Windows NT</td>
<td>Both</td>
</tr>
<tr>
<td>mycomapp.dsp</td>
<td>The file that contains the mycomapp settings.</td>
<td>Windows NT</td>
<td>Both</td>
</tr>
<tr>
<td>mycomapp.idl</td>
<td>The interface definition language file, which describes the interfaces specific to your objects.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>mycomapp.rc</td>
<td>The resource file, which initially contains the version information and a string containing the mycomapp name.</td>
<td>Windows NT</td>
<td>Both</td>
</tr>
<tr>
<td>Resource.h</td>
<td>The header file for the resource file.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>mycomappps.mk</td>
<td>The make file that can be used to build a proxy/stub DLL. You do not need this file.</td>
<td>Windows NT</td>
<td>Proxy/stub</td>
</tr>
<tr>
<td>mycomappps.def</td>
<td>The module definition file for the proxy/stub DLL. <strong>Note:</strong> MYCOMAPPPS.DEF becomes MYCOMAPPPSS$SHR.OPT on OpenVMS.</td>
<td>Windows NT</td>
<td>Proxy/stub</td>
</tr>
<tr>
<td>StdAfx.cpp</td>
<td>The file that will include the ATL implementation files.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>StdAfx.h</td>
<td>The file that will include the ATL header files. To make the mycomapp DLL useful, you need to add a control, using the ATL Object Wizard.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>mycomapp.rgs</td>
<td>A registrar script for your COM server.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
</tbody>
</table>

(continued on next page)
### 9.2 Developing a COM for OpenVMS Application Using ATL

Table 9–2 (Cont.) Files Generated by ATL COM AppWizard for *mycomapp*

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
<th>Platform</th>
<th>In-Process or Out-of-Process</th>
</tr>
</thead>
<tbody>
<tr>
<td>myinterface.rgs</td>
<td>A registrar script for your COM server.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>myinterface.cpp</td>
<td>The interfaces specific to your object.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
<tr>
<td>myinterface.h</td>
<td>The header file for the interfaces.</td>
<td>Windows NT/OpenVMS</td>
<td>Both</td>
</tr>
</tbody>
</table>

### 9.2.2 Step 2: Modify Generated Files for ATL Applications on OpenVMS

Make the following changes to the generated files before you build ATL applications on OpenVMS.

#### 9.2.2.1 Remove _ATL_MIN_CRT

When the ATL COM AppWizard generates *mycomapp*, it also defines the macro _ATL_MIN_CRT as part of the GUI support. Because OpenVMS does not have a graphical interface, you must remove (or not define) _ATL_MIN_CRT when you build on OpenVMS.

#### 9.2.2.2 Include ATLMAIN.CXX

On OpenVMS, you must include ATLMAIN.CXX for out-of-process components. ATLMAIN.CXX defines the wWinMain() function.

#### 9.2.2.3 Modify Registration Procedure

OpenVMS does not support registering the application using the UpdateRegistryFromFile function. You must use the OpenVMS UpdateRegistryFromFile function in the ATLBASE.H header file. You must make the necessary changes to your application. The following table shows the changes you must make.

<table>
<thead>
<tr>
<th>File to search</th>
<th>Search for</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface header file</td>
<td>DECLARE_REGISTRY_RESOURCEID</td>
<td>DECLARE_REGISTRY_FILE</td>
</tr>
<tr>
<td>Project source file</td>
<td>_Module.UpdateRegistryFromFile</td>
<td>_Module.UpdateRegistryFromFile</td>
</tr>
</tbody>
</table>

The following example shows sample coding changes.

```
#ifdef __vms
DECLARE_REGISTRY_FILE(_T("MYINTERFACE.RGS"))
#else
DECLARE_REGISTRY_RESOURCEID(IDR_MYINTERFACE)
#endif

#ifdef __vms
_Module.UpdateRegistryFromFile(_T("MYCOMAPP.RGS"), TRUE);
#else
_Module.UpdateRegistryFromFile(IDR_MYCOMAPP, TRUE);
#endif
```
9.2 Developing a COM for OpenVMS Application Using ATL

9.2.3 Step 3: Build an Application Using the MIDL Compiler

This process is the same as shown in Section 7.2.

For example (in-process):

$ MIDL := $DCOM$MIDL.EXE
$ MIDL -nologo -Oicf mycompapp.idl -
 -IDCOM$LIBRARY -
 -iid mycompapp_i.c -
 -proxy mycompapp_p.c -
 -dlddata dlddata.c -
 -tlb mycompapp$shr.tlb

For example (out-of-process):

$ MIDL := $DCOM$MIDL.EXE$ MIDL -nologo -Oicf mycompapp.idl -
 -IDCOM$LIBRARY -
 -iid mycompapp_i.c -
 -proxy mycompapp_p.c -
 -dlddata dlddata.c -
 -tlb mycompapp.tlb

Compaq recommends that the name of your type library match the name of your executable or shareable image.

9.2.4 Step 4: Compile the ATL COM Application

The following sections describe how to compile COM for OpenVMS applications.

9.2.4.1 Required Header File: ATLBASE.H

The VMS_ATL.H header file defines several macros used by the Wind/U header files. VMS_ATL.H is already included in the ATLBASE.H header file. When creating ATL source code, you must include ATLBASE.H as the first noncommented line in your source (both header and implementation) files.

9.2.4.2 Required Macro Definitions

Include the following /DEFINE qualifier on all of your C and CXX commands:

/DEFINE=(UNICODE=1,_WINDU_SOURCE=0X041000,_WIN32_DCOM,_ATL_STATIC_REGISTRY)

The UNICODE macro ensures that wide-character variants of Win32 APIs and data structures are enabled when you compile. (The UNICODE macro is also defined in VMS_DCOM.H.) If you omit the UNICODE macro, your compile fails when you build using the Wind/U Win32 environment.

The other two macro definitions are recognized by the Wind/U header files and are required to ensure the proper definition of structures and COM APIs.

The _ATL_STATIC_REGISTRY macro enables you to statically link with the ATL registry component (Registrar) for optimized Registry access. You can add the macro either by including the /DEFINE qualifier on the command line or by adding the stdafx.h header file to your code.

9.2.4.3 Required Include Directories

COM for OpenVMS applications typically require header files that come from DCOM$LIBRARY. The ATL header files and source files are also located in DCOM$LIBRARY.

Include the following qualifier on your C and CXX command lines:

/INCLUDE=DCOM$LIBRARY
If you already have an /INCLUDE qualifier on your command line, modify the command to include DCOM$LIBRARY.

### 9.2.4.4 Required C++ Qualifiers

You must specify the following C++ qualifiers when you build COM for OpenVMS applications:

- **/EXCEPTIONS=CLEANUP**
  
  Specify the /EXCEPTIONS=CLEANUP qualifier on C++ commands to enable C++ exceptions.

- **/STANDARD=MS**
  
  The C++ compiler supports many different compilation standards. You must use /STANDARD=MS for COM applications created by ATL. /STANDARD=MS informs the compiler that it should follow the language constructs supported by the Visual C++ compiler. This switch works well with the code generated by ATL.

- **/TEMPLATE_DEFINE=(NOALL, NOPRAGMA)**
  
  This switch controls the instantiation of C++ templates. You must specify the following options:

  - **[NO]ALL**
    
    Instantiate all function template entities declared or referenced in the compilation unit, including typedefs. For each fully instantiated template class, all its member functions and static data members are instantiated even if they were not used. Nonmember template functions are instantiated even if the only reference was a declaration. Instantiations are created with external linkage. Overrides /REPOSITORY at compile time. The compiler places instantiations in the user's object file. The template definition must be present before the point of each instantiation in the source file.

    The default is /TEMPLATE_DEFINE=NOALL.

  - **[NO]PRAGMA**
    
    Determines whether the C++ compiler ignores #PRAGMA DEFINE_TEMPLATE directives encountered during the compilation. This option lets you quickly switch to automatic instantiation without having to remove all the pragma directives from your program's code base.

    The default is /TEMPLATE_DEFINE=PRAGMA, which enables #PRAGMA DEFINE_TEMPLATE.

### 9.2.5 Step 5: Link the ATL COM Application

To build a COM for OpenVMS application, you must build both client and component images. Because you can implement a component as either an in-process component or an out-of-process component, you must build either a shareable image or an executable image, or both.

The following sections describe the steps you must follow to link the client, component, and proxy/stub images.
9.2 Developing a COM for OpenVMS Application Using ATL

9.2.5.1 Linking the Client and the Out-of-Process Component

Although you do not need to specify any qualifiers to link the client or the component executable images, you must link both images. The specific link-time dependency is as follows:

- DCOM$LIBRARY:DCOM.OPT

If you have one or more C++ modules, use the C++ linker (CXXLINK) instead of the standard OpenVMS linker so you can specify the location of your C++ repository (/CXX_REPOSITORY qualifier). For example:

```bash
$ CXXLINK/your-specific-linker-qualifiers list-of-object-modules, -
$_$ DCOM$LIBRARY:DCOM.OPT/OPTIONS, application.OPT/OPTIONS -
$_$ /REPOSITORY=[.CXX_REPOSITORY]
```

You can also include the list of object modules in an options file instead of on the command line.

9.2.5.2 Linking the In-Process Component Shareable Image

The in-process component shareable image dependency list differs slightly from that of the client and component executables. The specific link-time dependencies are as follows:

- [directory-name]MYCOMPAPP$SHR.OPT
- DCOM$LIBRARY:DCOM.OPT

9.2.5.3 Creating a Symbol Vector

Use the procedure described in Section 7.4.2.1 to create a symbol vector for the in-process component shareable image.

Use the procedure described in Section 7.4.3 to create a symbol vector for the proxy/stub shareable image.

9.3 ATL Samples

TESTATL is an out-of-process sample, and MATH101 is an in-process sample.

You can find the sample ATL applications shown in this chapter in the following directories on the COM for OpenVMS kit:

- DCOM$EXAMPLES:[TESTATL_OUTPROC]
- DCOM$EXAMPLES:[TESTATL_INPROC]

Note

If you are running authenticated COM, before you build the application on OpenVMS, you must run NTASLOGON and acquire Windows NT credentials. For more information, see Section 8.2.

9.3.1 Out-of-Process COM Sample (TESTATL_OUTPROC)

This sample implements a COM client and server in which the component provides one interface: ISum.

Given sources initially generated by the Microsoft Visual Studio ATL AppWizard and a few applied changes, the sample demonstrates the build, registration, and execution of the ATL application on OpenVMS.
The following sections describe how to create the application using the Microsoft ATL AppWizard on Windows NT and how to build the application on an OpenVMS system.

9.3.1 Creating the Application on Windows NT
Use the following guidelines when generating a skeleton project and simple objects using the Microsoft Visual Studio ATL AppWizard.

• Generate the skeleton project
  - Select the ATL COM AppWizard and name your skeleton project.
  - Choose **Executable (EXE)** as the server type.

• Add objects
  - Start the ATL Object Wizard.
  - From the **Objects** category, select **Simple Object**.
    - From the **Attribute** tab, choose the **Both** threading model.

9.3.2 In-Process COM Sample (TESTATL_INPROC)
This sample implements a COM client and server in which the component provides three interfaces: ISum, IDiv, and IMul.

Given sources initially generated by the Microsoft Visual Studio ATL AppWizard, the sample demonstrates the build, registration, and execution of the shareable application on an OpenVMS system.

The following sections describe how to build the application.

9.3.2.1 Creating the Application on Windows NT
Use the following guidelines when generating a skeleton project and simple objects using the Microsoft Visual Studio ATL AppWizard.

• Generate the skeleton project
  - Select the ATL COM AppWizard and name your skeleton project.
  - Choose **Dynamic Link Library (DLL)** as the server type.

• Add objects
  - Start the ATL Object Wizard.
  - From the **Objects** category, select **Simple Object**.
    - From the **Attribute** tab, choose the **Both** threading model.

9.3.2.2 Building, Registering, and Running the Application on OpenVMS
A README file describes how to build, register, and run this COM for OpenVMS sample. The file is located in:

```
DCOM$EXAMPLES:[TESTATL_INPROC]README-TESTATL_INPROC.TXT
```
9.4 Suggested Reading

The following resources can provide you with more information about ATL:

- Third-party books about ATL:

  - The Component Object Model Specification, available from the Microsoft COM website:
    
    www.microsoft.com/com
Part II

OpenVMS Registry

The following chapters describe the OpenVMS Registry database, its structure, and the $REGISTRY and $REGISTRYW system services that interface with the OpenVMS Registry.
10.1 What is the Registry?

The Windows NT Registry is a single, systemwide, hierarchical database of configuration information about hardware and software (both the operating system and applications). The Windows NT Registry replaced Windows 3.x .ini files, providing a single place for storing application and configuration information.

To allow OpenVMS and Windows NT to interoperate, Compaq has provided a registry on OpenVMS. Like the Windows NT Registry, the OpenVMS Registry is made up of two components: the OpenVMS Registry database and the OpenVMS Registry server. The OpenVMS Registry database is a systemwide or clusterwide hierarchical database of configuration information. This information is stored in a database structure of keys and associated values. The OpenVMS Registry server controls all OpenVMS Registry operations, such as creating and backing up the OpenVMS Registry database, and creating, displaying, modifying, or deleting keys and values.

The OpenVMS Registry includes interfaces (COM APIs and system services) to allow applications to control the OpenVMS Registry server and to read and write to the OpenVMS Registry database. The OpenVMS Registry also includes server management utilities to allow system managers to display and update OpenVMS Registry information from the OpenVMS DCL command line.

The OpenVMS Registry is compatible with the Windows NT Registry. Windows NT client applications such as RegEdt32 can connect to and edit the OpenVMS Registry.

10.1.1 Suggested Reading

The following resources can provide you with more information about Windows NT Registry and related topics:

- Third-party books about the Windows NT Registry:

10.2 OpenVMS Registry Concepts and Definitions

The OpenVMS Registry, like the Windows NT Registry, is a hierarchical database with several branches.

The following sections list and explain OpenVMS Registry database elements and operation.
10.2 OpenVMS Registry Concepts and Definitions

10.2.1 Keys, Subkeys, and Values

A key is one of the basic building blocks of the OpenVMS Registry database. A key contains information specific to the computer, system, or user; it is a header field in the OpenVMS Registry database. Keys can be arranged in a hierarchy (or tree).

There are two main (or root) keys in the OpenVMS Registry:

- HKEY_USERS contains information about each user.
- HKEY_LOCAL_MACHINE contains hardware, software, security, and general system configuration information.

The key HKEY_CLASSES_ROOT points to the CLASSES subkey in HKEY_LOCAL_MACHINE. These root keys are discussed in more detail in Section 10.3.

A subkey is a key that is a child to another key. A key can have zero or more subkeys. Subkeys allow you to group related keys together below another key in a hierarchy or tree.

A value entry (or value) is a named element of data; it is a record field in the registry database. A key has zero or more associated values. A value has a value name, a value type, a collection of flags, and associated data (defined by the value's type). OpenVMS Registry supports the following value types:

- Null-terminated string
- Null-terminated array of null terminated strings
- Null-terminated string containing environment variables (logical names or symbols)
- 32-bit data item
- 64-bit data item
- Raw binary

Figure 10–1 summarizes the relationship between keys, subkeys, and values.

Figure 10–1  Key, Subkey, and Value Relationships

```
Key1=Value1
Key2
  +-Subkey1=Value1
  |    +-Subkey2=Value1,Value2
  |
```

10.2.1.1 Key and Value Volatility

You can define OpenVMS Registry keys and values as either nonvolatile or volatile. Nonvolatile keys are saved to OpenVMS Registry files. Volatile keys are cached to a temporary file.

On Windows NT systems, volatile keys and values are removed when the system restarts.
On OpenVMS, volatile keys and values are automatically removed when all nodes in a cluster are rebooted. OpenVMS extends the lifetime of volatile keys to survive server failover but not a cluster reboot. (In a standalone system, volatile keys and values are lost when the system reboots.)

10.2.1.2 Key Write-through and Write-behind

When you create a key, you can specify when the OpenVMS Registry should write that key's changed information. The write options are as follows:

- **Write-through**: Write the changes to disk immediately.
- **Write-behind**: Cache the changes and write them later.

The Cache Action attribute allows you to specify a key's write characteristics. If you do not specify the cache action attribute when you create the key, the key inherits this attribute from its parent.

When you use the **SYS$REGISTRY** interface, you can use the **REGSM_NOW** function code modifier for a request in progress to force an immediate write (write-through), regardless of the cache action attribute value.

10.2.1.3 Linking a Key to Other Keys and Values

OpenVMS Registry keys can link to other OpenVMS Registry keys, providing multiple paths to the same piece of data. In the same way, OpenVMS Registry values can link to other OpenVMS Registry values. These key and value links, or **symbolic links**, are similar to file links. Symbolic links are name references.

For example, you can link Key A to Key B. When you query Key A and its value, the system returns Key B's value.

You can also **chain** symbolic links. That is, Key A can point to Key B and Key B can point to Key C; as a result, Key A also points to Key C. You can specify a link through the $REGISTRY system service or through the OpenVMS Registry server management command-line interface.

10.2.1.4 Rules for Creating OpenVMS Registry Keys and Value Names

The following rules apply to key and value names:

- A key can have subkeys and values.
- A key name can be composed of any Unicode (4 bytes) character except the backslash (\) character and the null character. You must specify at least one character.
- A value name can be composed of any Unicode (4 bytes) character.
- A key string can be either a name (for example, disk) or a path (for example, Hardware\cosmos\disk).
- A value string can be a name only.
- When you define a key, if you specify a path but the system does not find one or more of the path subkeys, the system creates these subkeys automatically. The created keys inherit the attributes of their parent.
- The key and value names are case preserved in the OpenVMS Registry database. Name comparisons are case insensitive unless you specify the **REGSM_CASESENSITIVE** function code modifier with calls to the $REGISTRY system service.
Overview of OpenVMS Registry

10.2 OpenVMS Registry Concepts and Definitions

- For pure binary data, the maximum size of a value is 1 MB (for Windows NT compatibility).

10.2.2 Class

The Class attribute allows you to store additional descriptive information with each key. For example, specifying Class text string could allow you store permitted data types with a specified key.

10.2.3 Hive

A hive is a collection of related keys, subkeys, and values stored in the OpenVMS Registry.

On Windows NT systems, a hive is stored in a single file in the %SystemRoot%\system32\config directory, along with an associated LOG file. Windows NT allows users to save hives to specified files on disk so that these files can be loaded at a later time.

On OpenVMS systems, the entire OpenVMS Registry database consists of two hives: REGISTRY$LOCAL_MACHINE.REG and REGISTRY$USERS.REG. OpenVMS does not support loading and unloading hives.

10.3 OpenVMS Registry Structure

To allow Windows NT applications to interface with the OpenVMS Registry database, the OpenVMS Registry database includes a subset of the Windows NT Registry predefined keys and subkeys.

The OpenVMS Registry includes the following predefined standard keys:

- HKEY_CLASSES_ROOT
  On Windows NT systems, this key is reserved for the definition of classes of documents and the properties associated with these classes.
  On OpenVMS systems, this key by default does not have any subkey or value. This entry point maps to the HKEY_LOCAL_MACHINE\SOFTWARE\Classes subkey.

- HKEY_USERS
  On Windows NT systems, the entries under this entry point define the default user configuration for users on the local system and the user configuration for the current user.
  On OpenVMS systems, this key by default does not have any subkey or value.

- HKEY_LOCAL_MACHINE
  The entries under this entry point are reserved for system configuration information.
  On Windows NT systems, this area contains information about the bus type, system memory, and installed hardware and software.
  On OpenVMS systems, this key has the following predefined subkeys:
    - Hardware
      On Windows NT systems, the system constructs the volatile subkeys of this key from the information gathered at boot time.
      On OpenVMS systems, this key does not have any subkey or value by default.
    - Security
On Windows NT systems, these keys contain all the security information for the local computer. The system owns the information in these keys and protects them accordingly.

On OpenVMS systems, this key by default does not have any subkey or value.

— Software

On Windows NT systems, this key contains information about the software on the local system that is independent of per-user configurations.

On OpenVMS systems, this key has the following predefined subkeys:

* Classes
* Compaq Computer Corporation
* Microsoft

— System

On Windows NT systems, this key contains information about devices and services.

On OpenVMS systems, this key has the following predefined subkeys:

* CurrentControlSet
  
  On Windows NT systems, this key contains information about Control, Enum, and Hardware Profiles and Services.
  
  On OpenVMS systems, this key is reserved for use by Advanced Server for OpenVMS.

* Registry
  
  This subkey does not exist on Windows NT systems. On OpenVMS systems, this key contains the OpenVMS Registry server configuration parameters in the form of subkeys and values. The predefined subkeys are as follows:

  + File Quotas
    
    This subkey is empty when you create the OpenVMS Registry database. A system manager can assign quota for each OpenVMS Registry database file by creating a value whose name is the name of the OpenVMS Registry file. If no value exists for a file, the OpenVMS Registry server uses the default value for the Default File Quota setting.
    
    For example, a system manager could use REG$CP to assign a 1 MB quota to the OpenVMS Registry REGISTRY$LOCAL_MACHINE.REG file by issuing the following command:
    
    $ MCR REG$CP
    
    REG> CREATE VALUE/NAME=REGISTRY$LOCAL_MACHINE/TYPE=DWORD/ -
    
    _REG> DATA=%D1000000 "hkey_local_machine\system\registry\File Quotas"

  + File Monitor
    
    This subkey is not used.

  + Priority
Overview of OpenVMS Registry

10.3 OpenVMS Registry Structure

This subkey is empty at OpenVMS Registry database creation. A system manager can change the priority of the OpenVMS Registry server on a specified node by creating a value whose name is the node name of the system in the cluster on which the OpenVMS Registry server resides.

For example, a system manager could use the REG$CP server management utility to assign a priority of 100 to node COSMOS by issuing the following command:

```
$ MCR REG$CP
REG> CREATE VALUE/NAME=COSMOS/TYPE=DWORD/DATA=%D100 -
REG> "hkey_local_machine\system\registry\Priority"
```

10.4 Reading and Writing to the OpenVMS Registry

You can read and write to the OpenVMS Registry in the following ways:

- Using COM for OpenVMS, through the COM APIs available on OpenVMS. This allows application programmers to enter, modify, and delete OpenVMS Registry keys and values.
- Through the $REGISTRY and $REGISTRYW system services and the OpenVMS Registry server management utility commands. This allows application programmers to enter, modify, and delete OpenVMS Registry keys and values. For more information, see Section 10.4.1.
- From Windows NT, through the Windows NT Registry APIs, or using RegEdt32 (the Windows NT Registry Editor). This allows Windows NT users to view and edit OpenVMS Registry keys and values.

10.4.1 $REGISTRY System Services

The OpenVMS Registry includes two OpenVMS system services that provide an interface to the OpenVMS Registry server. The OpenVMS Registry system services allow you to query, update, and create keys, subkeys, and values in the OpenVMS Registry database.

For more information about the $REGISTRY and $REGISTRYW system services, see Chapter 13.

10.4.2 REG$CP Server Management Utility

The REG$CP server management utility allows you to display and update OpenVMS Registry information from the OpenVMS DCL prompt. The utility also allows you to back up and restore the entire OpenVMS Registry database to or from a file, as long as you have the required system privileges.

For more information about the REG$CP server management utility, see Chapter 12.

10.5 OpenVMS Registry Security

The OpenVMS Registry implements both the OpenVMS and Windows NT security models.

To access to the OpenVMS Registry database, the calling process must have the proper OpenVMS Registry rights identifier for the operation you want to perform (for example, REG$LOOKUP for read operations, REG$UPDATE for write operations, or REG$PERFORMANCE for statistics operations) or the calling process must have the SYSPRV privilege.

10–6 Overview of OpenVMS Registry
The following sections describe the two models.

10.5 OpenVMS Registry Security

10.5.1 OpenVMS Security Model

When a user requests access to the OpenVMS Registry, the OpenVMS system checks the user’s Windows NT credentials and allows access as follows:

1. Does the user have Windows NT credentials?
   - If the user has Windows NT credentials because the user has connected to OpenVMS from a Windows NT system, OpenVMS allows the user access to the OpenVMS Registry based on the user’s supplied credentials.
   - If the user has Windows NT credentials because the user is a COM Version 1.1-B for OpenVMS client, OpenVMS allows the user access to the OpenVMS Registry based on the user’s supplied credentials.
   - If the user has Windows NT credentials because the user has logged on to OpenVMS through single signon, OpenVMS allows the user access to the OpenVMS Registry based on the user’s supplied credentials.
   - If the user is not allowed access to the OpenVMS Registry based on the user’s supplied credentials, skip to Step 2.
   - If the user does not have Windows NT credentials, continue to the next step.

2. Does the user have the OpenVMS SYSPRV privilege?
   - If the user has the SYSPRV privilege, OpenVMS allows the user full access to the OpenVMS Registry.
   - If the user does not have the SYSPRV privilege, continue to the next step.

3. Does the user have the REG$UPDATE, REG$LOOKUP, or REG$PERFORMANCE rights identifier?
   - If the user has the REG$UPDATE, REG$LOOKUP, or REG$PERFORMANCE rights identifier, OpenVMS allows the user access to the OpenVMS Registry using the supplied rights identifier. The user can access the OpenVMS Registry database as follows:
     - REG$UPDATE: Allows full access to the OpenVMS Registry except for maintenance requests.
     - REG$LOOKUP: Allows read-only access to the OpenVMS Registry.
     - REG$PERFORMANCE: Allows access to performance data collected by the OpenVMS Registry server.
   - If the user does not have the REG$UPDATE, REG$LOOKUP, or REG$PERFORMANCE rights identifier, continue to the next step.

4. If the user has no Windows NT credentials, OpenVMS grants the OpenVMS user Windows NT Everyone group access. In this case, the OpenVMS user’s access to OpenVMS Registry keys depends on what permissions the key owner defined for Everyone when the key owner created the key or subkey. Based on these permissions, the OpenVMS user will be able to do one of the following:
   - Read the key and its subkeys.
   - Not see the key and its subkeys.
10.5.1.1 Granting OpenVMS Registry Access Rights Using the AUTHORIZE Utility

You can use the OpenVMS Authorize utility (AUTHORIZE) to add the SYSPRV privilege and REG$UPDATE, REG$LOOKUP, and REG$PERFORMANCE identifiers to user processes.

__________________________ Caution ______________________________

Granting OpenVMS Registry rights overrides Windows NT security access checks.

Because rights identifiers are specific to an application, you cannot use the AUTHORIZE command to create the rights identifiers. Use the REG$CP server management utility to create these rights on your system. Running the REG$CP server management utility creates these rights by default. You must run REG$CP from a privileged account. For more information about running REG$CP, see Chapter 12.

The following example shows how to use the SET RIGHTS_LIST command to allow all users to view keys and data in the OpenVMS Registry database. This command adds the REG$LOOKUP identifier to the system rights list.

$ SET RIGHTS_LIST/ENABLE/SYSTEM REG$LOOKUP

Example 10–1 shows how to use AUTHORIZE to grant and remove OpenVMS Registry rights to a specific user.

Example 10–1 Using AUTHORIZE to Grant Rights to a User

$ SET DEF SYS$SYSTEM
$ RUN AUTHORIZE

UAF> GRANT/IDENTIFIER REG$LOOKUP SMITH ①
UAF> GRANT/IDENTIFIER/ATTRIBUTES=DYNAMIC REG$UPDATE SMITH ②
UAF> REVOKE/IDENTIFIER REG$UPDATE SMITH ③
UAF> GRANT/IDENTIFIER REG$PERFORMANCE SYSTEM ④

① This AUTHORIZE command grants the REG$LOOKUP identifier to user Smith, allowing Smith to view keys and data in the OpenVMS Registry database.

② This AUTHORIZE command grants the REG$UPDATE identifier to user Smith, allowing Smith to modify keys and data in the OpenVMS Registry database. The dynamic attribute allows Smith to remove or restore the REG$UPDATE identifier from the process rights list by using the SET RIGHT/ENABLE or the SET RIGHT/DISABLE command.

③ This AUTHORIZE command removes the REG$UPDATE identifier from user Smith.

④ This AUTHORIZE command grants the REG$PERFORMANCE identifier to the system manager account, allowing the system manager to enable and disable the monitoring of OpenVMS Registry performance data.
10.5.2 Windows NT Security Model

Windows NT users can access the OpenVMS Registry only through the Advanced Server for OpenVMS. OpenVMS grants Windows NT users access to the OpenVMS Registry based on the user’s Windows NT credentials.

10.6 Controlling the OpenVMS Registry Server Operations

OpenVMS Registry server operations include control of file quotas, server priority, error recovery actions, frequency of database backup, and OpenVMS Registry server tuning.

The following sections describe OpenVMS Registry server operations, and provide minimum, maximum, and default values for each setting. For information about how to change these settings, see Chapter 12.

10.6.1 Defining Maximum Reply Age/Age Checker Interval Settings

The OpenVMS Registry server handles duplicate requests by tracking work in progress and returning a REG$_DUPLREQUEST error. The OpenVMS Registry server also holds completed requests in case a duplicate request is received for work that is already completed. In this case, the OpenVMS Registry server reconstructs the reply. After a specified time, the requests are discarded. The **Maximum Reply Age** setting determines how long these requests are retained. The **Age Checker Interval** setting determines how often the OpenVMS Registry server checks for requests that exceed this age.

By default, the server checks for old completed requests every five seconds. By default, the server discards completed requests that are older than five seconds.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Reply Age</td>
<td>5</td>
<td>1</td>
<td>60</td>
</tr>
<tr>
<td>Age Checker Interval</td>
<td>5</td>
<td>1</td>
<td>60</td>
</tr>
</tbody>
</table>

10.6.2 Defining the Database Log Cleaner Interval/Initial Log File Size Settings

The OpenVMS Registry uses a two-phase commit process to write modifications to the OpenVMS Registry database. The OpenVMS Registry first writes the modifications to a log file and then applies the log file to the OpenVMS Registry database. The **Database Log Cleaner Interval** setting determines how often the OpenVMS Registry applies the log file to the OpenVMS Registry database. After the OpenVMS Registry applies the log file, the OpenVMS Registry creates a new log file based on the size you specify in the **Initial Log File Size** setting.

The **Database Log Cleaner Interval** setting should be short enough so that writes to the database do not require that the log file be extended. Also, the log file size should be small to keep the amount of time spent applying the log relatively short, because this operation blocks writes to the database.

By default, the log file is applied every five seconds. By default, the OpenVMS Registry log file is created using a size of 32 blocks (16 KB).

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Log Cleaner Interval</td>
<td>5</td>
<td>1</td>
<td>30</td>
</tr>
<tr>
<td>Initial Log File Size</td>
<td>32</td>
<td>16</td>
<td>256</td>
</tr>
</tbody>
</table>
10.6.3 Defining Default File Quota/File Quota Interval Settings

The OpenVMS Registry server limits the size of OpenVMS Registry database files by applying file quotas. You can assign file quotas to the individual files that make up the OpenVMS Registry database. If you do not assign a file quota, the OpenVMS Registry uses the Default File Quota setting.

The OpenVMS Registry server periodically recalculates the size of the OpenVMS Registry database files to see whether quota is exceeded. The File Quota Interval setting determines how often the OpenVMS Registry performs this calculation.

By default, the Default File Quota setting is 10 MB. By default, the server recalculates the file quota every 30 seconds.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default File Quota</td>
<td>0x10000000</td>
<td>0x7d00</td>
<td>0x3ffffff</td>
</tr>
<tr>
<td>File Quota Interval</td>
<td>30</td>
<td>10</td>
<td>60</td>
</tr>
</tbody>
</table>

10.6.4 Defining the Scan Interval Setting

In an OpenVMS Cluster, you can run OpenVMS Registry servers on more than one node; however, only one OpenVMS Registry server is active at a time. A OpenVMS Registry server’s priority relative to the other OpenVMS Registry servers in the cluster determines which OpenVMS Registry server is active. If the cluster configuration changes, the system manager can adjust the priority of one or more OpenVMS Registry servers. After the system manager changes the priority, the OpenVMS Registry servers in the cluster determine which server now has the highest priority and automatically change their states as necessary. The Scan Interval setting determines how often a OpenVMS Registry server checks for changes in its priority.

By default, a server checks for changes in priority every 120 seconds.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Interval</td>
<td>120</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>

10.6.5 Defining the Log Registry Value Error Setting

The OpenVMS Registry server logs an error if one of the OpenVMS Registry server parameter values is out of the acceptable range. If the OpenVMS Registry detects an out-of-range error, the OpenVMS Registry server uses the default value for that parameter. The Log Registry Value Error setting is a Boolean value that determines whether the error should be logged.

By default, the OpenVMS Registry server does not log out-of-range errors.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log Registry Value Error</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
10.6.6 Defining the Operator Communications Interval Setting

If an I/O error occurs, the OpenVMS Registry server can display a message to the operator console using OPCOM. The **Operator Communications Interval** setting determines how long the OpenVMS Registry server waits after the I/O error to determine if the error is going to persist. If the error does persist, OpenVMS Registry writes a message to the operator console.

By default, the OpenVMS Registry server writes a message to the operator console if the error persists longer than 60 seconds.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age Checker Interval</td>
<td>5</td>
<td>1</td>
<td>60</td>
</tr>
<tr>
<td>Operator Communication Interval</td>
<td>60</td>
<td>30</td>
<td>120</td>
</tr>
</tbody>
</table>

10.6.7 Defining the Process Time Limit Setting

The OpenVMS Registry server writes a message to the server log file if it takes too long to process a request. The **Process Time Limit** setting determines when a request has taken too long.

By default, 180 seconds are allowed per request before the OpenVMS Registry logs a message.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process Time Limit</td>
<td>180</td>
<td>60</td>
<td>600</td>
</tr>
</tbody>
</table>

10.6.8 Defining the Reply Log Cleaner Interval Setting

The OpenVMS Registry server maintains a log of recent replies that it uses to reconstruct work in progress in the case of failover. After a specified time, the server discards these replies. The **Reply Log Cleaner Interval** setting determines how often the OpenVMS Registry discards these replies.

By default, the OpenVMS Registry server discards replies every five seconds.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reply Log Cleaner Interval</td>
<td>10</td>
<td>5</td>
<td>60</td>
</tr>
</tbody>
</table>

10.6.9 Defining Snapshot Interval/Snapshot Location/Snapshot Versions Settings

The OpenVMS Registry server maintains backup copies of the OpenVMS Registry database. The **Snapshot Interval** setting determines how often the OpenVMS Registry server creates a backup copy. The **Snapshot Location** setting determines where the OpenVMS Registry stores the copy. The **Snapshot Versions** setting determines how many previous copies the OpenVMS Registry keeps.

By default, the OpenVMS Registry database is copied to backup once per day. By default, the OpenVMS Registry database is copied to the location determined by the definition of the SYS$REGISTRY logical name. By default, the OpenVMS Registry keeps five previous versions of the OpenVMS Registry database.
Overview of OpenVMS Registry
10.6 Controlling the OpenVMS Registry Server Operations

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Snapshot Interval</td>
<td>86400</td>
<td>3600</td>
<td>604800</td>
</tr>
<tr>
<td>Snapshot Location</td>
<td>SYS$REGISTRY</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Snapshot Versions</td>
<td>5</td>
<td>1</td>
<td>10</td>
</tr>
</tbody>
</table>

10.6.10 Defining the Write Retry Interval Setting

In the OpenVMS Registry finds an error when writing to the OpenVMS Registry database, the OpenVMS Registry server retries the write at an interval specified by the Write Retry Interval setting.

By default, the OpenVMS Registry server attempts to retry failed writes to the OpenVMS Registry database every five seconds.

<table>
<thead>
<tr>
<th>Setting Name</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Writer Retry Interval</td>
<td>5</td>
<td>1</td>
<td>30</td>
</tr>
</tbody>
</table>
11.1 Installing the OpenVMS Registry

The OpenVMS Registry server is installed as part of the OpenVMS Version 7.2-1 system installation.

Before you can use the OpenVMS Registry, you must configure the OpenVMS Registry server and populate the OpenVMS Registry database. For more information about configuring the OpenVMS Registry server, see Section 11.2. For more information about populating the OpenVMS Registry database, see Section 6.2.

The first time you start the OpenVMS Registry server using the startup process described in Section 11.3, the OpenVMS system creates the OpenVMS Registry database.

You can access the OpenVMS Registry in several ways. Depending on how you want to access the OpenVMS Registry, you must install the following products:

- If you want to access the OpenVMS Registry using the COM APIs, you must install COM for OpenVMS. For more information, see Chapter 4.
- If you want to access the OpenVMS Registry using the Windows NT application RegEdt32, you must first install, configure, and start Advanced Server for OpenVMS. For more information, see the Advanced Server for OpenVMS documentation.

You can also access the OpenVMS Registry using the OpenVMS Registry server management utility or the OpenVMS Registry system services, which are installed as part of the OpenVMS Registry in OpenVMS Version 7.2-1.

11.2 Configuring the OpenVMS Registry: the REG$CONFIG Configuration Utility

The OpenVMS Registry Configuration utility (REG$CONFIG) provides information about the OpenVMS Registry server status and the OpenVMS Registry database location, and allows you to change OpenVMS Registry logical names and paths.

Enter the following command to start the OpenVMS Registry Configuration utility:

$ @SYS$MANAGER:REG$CONFIG
OpenVMS Registry System Management
11.2 Configuring the OpenVMS Registry: the REG$CONFIG Configuration Utility

The system displays the following menu:

---------------------------------------------------------
OpenVMS Registry Configuration Utility
---------------------------------------------------------
1 - Configure OpenVMS Registry logical names and directory paths
2 - Display OpenVMS Registry logical names and directory paths
3 - Check the state of the OpenVMS Registry server
4 - Start the OpenVMS Registry server on this node
H - Help about this utility
[E] - Exit

Please enter your choice:
---------------------------------------------------------

To select an option, enter the option number. The options are as follows:

- 1 - Configure OpenVMS Registry logical names and directory paths
  Allows you to configure the OpenVMS Registry server startup value and specify the location of the OpenVMS Registry database.
  For this procedure, see Section 11.2.1.

- 2 - Display OpenVMS Registry logical names and directory paths
  Displays the current values of the OpenVMS Registry server logical (startup value) for this node and the OpenVMS Registry database location.

- 3 - Check the state of the OpenVMS Registry server
  Displays the current state of the OpenVMS Registry server. The system displays one of the following:
  The OpenVMS Registry server is started in the cluster.
  The OpenVMS Registry server is started on this node.
  The OpenVMS Registry server is not started.

- 4 - Start the OpenVMS Registry server on this node
  Starts the OpenVMS Registry server on the current node. The system displays the following message:
  The OpenVMS Registry server has successfully started.

- H - Help about this utility
  Displays online help for OpenVMS Registry Configuration utility options.

- [E] - Exit
  Exits the OpenVMS Registry Configuration utility.

Tip: Enter Q (Quit) at any time

You can enter Q at any prompt to return to the OpenVMS Registry Configuration utility menu.

If you quit while you are configuring logical names, the system updates only those values for which you have received a confirmation message.
### 11.2.1 Configuring OpenVMS Registry Values

The system displays the following questions:

1. The system prompts you to enter standalone or cluster information. The system displays the following message:

   Is this system now a node in a cluster or will this system become part of a cluster? (Y/N/Q):

   ![Message](image)

2. The system displays the current information about the **REG$TO_BE_STARTED** logical, then prompts you to change the value.

   ![Logical Table](image)

   **NOTE:** Setting this logical to TRUE starts the OpenVMS Registry server automatically when the system boots. Setting this logical to FALSE prevents the OpenVMS Registry server from starting when the system boots and prevents other products from starting the OpenVMS Registry server. If the OpenVMS Registry Server is not started at boot time, but other products that require an OpenVMS Registry server are able to start the OpenVMS Registry server, you do not need to assign a value to this logical.

Do you want to change this value? (Y/N/Q) [Y]:

If you choose Y, the system prompts you for the new value.

Enter the new value (TRUE/FALSE/NOVAL/Q):

Enter one of the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Start the OpenVMS Registry server on reboot. Allow other products to start the server.</strong></td>
<td>TRUE</td>
</tr>
<tr>
<td><strong>Do not start the OpenVMS Registry server on reboot. Do not allow other products to start the server.</strong></td>
<td>FALSE</td>
</tr>
<tr>
<td><strong>Do not start the OpenVMS Registry server on reboot. Allow other products to start the server. (Deassigns the logical name.)</strong></td>
<td>NOVAL</td>
</tr>
<tr>
<td><strong>Quit this procedure and return to the OpenVMS Registry Configuration utility menu.</strong></td>
<td>Q</td>
</tr>
</tbody>
</table>

In which logical name table do you want the logical defined? (SYSTEM/SYSCluster/CLUSTER/Q) :

Enter one of the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add the REG$TO_BE_STARTED logical to the LNMS$SYSTEM logical name table. This table contains names that are shared by all processes in the system.</strong></td>
<td>SYSTEM</td>
</tr>
<tr>
<td><strong>Add the REG$TO_BE_STARTED logical to the LNMS$SYSCLUSTER logical name table. This table contains names that are shared by all processes in an OpenVMS Cluster.</strong></td>
<td>SYSCluster</td>
</tr>
<tr>
<td><strong>Add the REG$TO_BE_STARTED logical to the LNMS$CLUSTER logical name table. This table is the parent table for all clusterwide logical name tables.</strong></td>
<td>CLUSTER</td>
</tr>
<tr>
<td><strong>Quit this procedure and return to the OpenVMS Registry Configuration utility menu.</strong></td>
<td>Q</td>
</tr>
</tbody>
</table>
After you enter the new or updated value, the system confirms the change and displays the line you must add to your SYLOGICALS.COM file.

The logical REG$TO_BE_STARTED has been temporarily defined.
Before you reboot the system you must edit your SYLOGICALS.COM to include the line:

```
DEFINE/TABLE=table-name REG$TO_BE_STARTED value
```

Press [Enter] to continue.

3. The system displays the current information about the SYS$REGISTRY logical, then prompts you to change the value.

```
- SYS$REGISTRY logical -

 current value of SYS$REGISTRY

Note: When the OpenVMS Registry server is started, the system creates an OpenVMS Registry database at this location.
If an OpenVMS Registry database already exists on your system, you must redefine the SYS$REGISTRY logical to point to the existing OpenVMS Registry database location.
```

Do you wish to change this value? (Y/N/Q) [Y]:

If you choose Y, the system prompts you for the new value.

Enter the new value for SYS$REGISTRY ("yourvalue"/NOVAL/Q):

Enter one of the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define a new or changed location for the OpenVMS Registry database.</td>
<td>A valid directory specification, such as DKAO:[SYS$REGISTRY].</td>
</tr>
<tr>
<td>Deassign the logical name.</td>
<td>NOVAL</td>
</tr>
<tr>
<td>Quit this procedure and return to the OpenVMS Registry Configuration utility menu.</td>
<td>Q</td>
</tr>
</tbody>
</table>

4. The system displays your updated value and prompts you to confirm the value.

```
You have entered: value
Is this correct? (Y/N/Q) [Y]:
```

5. The system prompts you to enter a logical table name in which to store the new or updated logical.

```
In which logical name table do you want the logical defined? (SYSTEM/SYSCLUSTER/CLUSTER/Q):
```

Enter one of the following:
11.2 Configuring the OpenVMS Registry: the REG$CONFIG Configuration Utility

<table>
<thead>
<tr>
<th>Action</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add the SYS$REGISTRY logical to the LNM$SYSTEM logical name table. This table contains names that are shared by all processes in the system.</td>
<td>SYSTEM</td>
</tr>
<tr>
<td>Add the SYS$REGISTRY logical to the LNM$SYSCLUSTER logical name table. This table contains names that are shared by all processes in an OpenVMS Cluster.</td>
<td>SYSCLUSTER</td>
</tr>
<tr>
<td>Add the SYS$REGISTRY logical to the LNM$CLUSTER logical name table. This table is the parent table for all clusterwide logical name tables.</td>
<td>CLUSTER</td>
</tr>
<tr>
<td>Quit this procedure and return to the OpenVMS Registry Configuration utility menu.</td>
<td>Q</td>
</tr>
</tbody>
</table>

After you enter the new or updated value, the system confirms the change and displays the line you must add to your SYLOGICALS.COM file.

The logical SYS$REGISTRY has been temporarily defined. Before you reboot the system you must edit your SYLOGICALS.COM file to include the line:

```
DEFINE/TABLE=table-name SYS$REGISTRY dir-spec
```

Press [Enter] to continue.

6. The system displays information about the location of the OpenVMS Registry database.

   - SYS$REGISTRY directory -

   [directory status]

If the directory does not exist, the system prompts you to create the directory.

!!Caution!! When the OpenVMS Registry server starts, the system creates an OpenVMS Registry database at this location. If you already have an OpenVMS Registry database on your system, you must redefine the SYS$REGISTRY logical to point to that location.

Do you wish to create the directory? (Y/N/Q) [Y]:

If you enter Y the system confirms the directory creation.

The SYS$REGISTRY directory has now been created.

Press [Enter] to return to the menu.

11.3 Starting the OpenVMS Registry

You can control how the OpenVMS Registry will start as follows:

- Start the OpenVMS Registry automatically when the system reboots.
- Have products that require the OpenVMS Registry to be running start the OpenVMS Registry.
- Start the OpenVMS Registry manually.
- Prevent the OpenVMS Registry from starting.

Use the OpenVMS Registry Configuration utility described in Section 11.2 to control how the OpenVMS Registry starts.
11.3 Starting the OpenVMS Registry

11.3.1 Starting the OpenVMS Registry Manually

Under some conditions, you might want to start the OpenVMS Registry server manually.

Compaq recommends that you use the SYSSSTARTUP:REG$STARTUP.COM command procedure. The following command procedure ensures that the server process quotas are set to the required minimum values:

$ @SYSSSTARTUP:REG$STARTUP.COM

Alternately, you can use the following command to start the OpenVMS Registry manually:

$ SET SERVER REGISTRY_SERVER/START

11.4 Shutting Down the OpenVMS Registry

The OpenVMS Registry server is shut down automatically as part of a system shutdown.

If you want to shut down the OpenVMS Registry manually, use the following command:

$ SET SERVER REGISTRY_SERVER/EXIT

11.5 OpenVMS Registry Server Commands

The OpenVMS Registry server commands allow you to display (SHOW) and change (SET) the state of the OpenVMS Registry server. The following sections list and describe the OpenVMS Registry server commands.
SHOW SERVER REGISTRY_SERVER

Show the current status of the OpenVMS Registry on a specified node.
This command requires the SYSPRV privilege.

Format

SHOW SERVER REGISTRY_SERVER

[/MASTER | /CLUSTER | /NODE=(node,...)]

[/PAGE]

Qualifiers

/MASTER
Displays the node and process ID (PID) of the current OpenVMS Registry master server in the cluster. This command does not communicate with the OpenVMS Registry servers in the cluster. Requires SYSLCK privilege as well as the SYSPRV privilege.

/CLUSTER
Returns the show output from each OpenVMS Registry server in the cluster, listing the OpenVMS Registry master server information first.

/NODE=(node,...)]
Returns OpenVMS Registry server information about the servers on the specified nodes, listed in the order in which you enter the node names. The node names you specify must be in the current cluster.

/PAGE
Displays the returned show output in a scrollable page display.
SET SERVER REGISTRY_SERVER

Change the state of the OpenVMS Registry.
This command requires the SYSPRV privilege.

Format

SET SERVER REGISTRY_SERVER
/[MASTER | /CLUSTER | /NODE=(node,...)]
/[START | /RESTART | /EXIT | /ABORT ]
/[NO]LOG

Qualifiers

/MASTER
Issues the specified command to the OpenVMS Registry master server only. Requires the SYSLCK privilege as well as the SYSPRV privilege.

/CLUSTER
Issues the SET command to each OpenVMS Registry server in the cluster, setting the OpenVMS Registry master server last.

/NODE=(node,...)
Issues the SET command to the OpenVMS Registry servers on the specified nodes, in the order in which you enter the node names. The node names must be in the current cluster.

/START=[(node,...)]
Starts the OpenVMS Registry server on the specified node or nodes in the cluster.

/EXIT=[(node,...)]
Stops the OpenVMS Registry server on the specified node or nodes in the cluster.

/ABORT=[(node,...)]
Aborts the OpenVMS Registry server on the specified node or nodes in the cluster.

/[NO]LOG
Creates a new OpenVMS Registry log file in SYS$REGISTRY. NOLOG is the default.
11.6 OpenVMS Registry Failover in a Cluster

To increase the availability and reliability of the OpenVMS Registry, you can run multiple OpenVMS Registry servers in a cluster, up to one per node. No matter how many OpenVMS Registry servers you run, you have only one OpenVMS Registry database.

When you run more than one OpenVMS Registry server in a cluster, only one OpenVMS Registry server process is active and writing to the OpenVMS Registry database. The other OpenVMS Registry server processes are standing by.

By default, the first OpenVMS Registry server process that is active in the cluster remains active until either the process no longer exists or the priority among OpenVMS Registry server processes changes.

11.6.1 Changing the Priority of OpenVMS Registry Server Processes

You can change the priority of OpenVMS Registry server processes by creating and modifying the priority value of each node in the cluster that will run the OpenVMS Registry server process: the higher the value, the higher the priority.

Example 11–1 shows priority values being assigned so that NODENAME1 will be the active OpenVMS Registry server process in the cluster.

Example 11–1 Setting Priority Values

```
$ mcr regscp
REG> CREATE VALUE HKEY_LOCAL_MACHINE\SYSTEM\REGISTRY\PRIORITY_
  _/NAME=NODENAME1/DATA=15/TYPEDWORD
REG> CREATE VALUE HKEY_LOCAL_MACHINE\SYSTEM\REGISTRY\PRIORITY_
  _/NAME=NODENAME2/DATA=10/TYPEDWORD
REG> CREATE VALUE HKEY_LOCAL_MACHINE\SYSTEM\REGISTRY\PRIORITY_
  _/NAME=NODENAME3/DATA=5/TYPEDWORD
```

In Example 11–1, if NODENAME1 shuts down, control of the OpenVMS Registry database passes to the server process on NODENAME2.

Example 11–2 shows the system manager increasing the priority value of NODENAME3 to 20.

Example 11–2 Changing Priority Values

```
$ mcr regscp
REG> MODIFY VALUE HKEY_LOCAL_MACHINE\SYSTEM\REGISTRY\PRIORITY_
  _/NAME=NODENAME3/DATA=20/TYPEDWORD
```

In Example 11–2, the OpenVMS Registry server process on NODENAME1 goes into standby mode and the OpenVMS Registry server process on NODENAME3 becomes active.

11.7 Connecting to the OpenVMS Registry from a Windows NT System

To connect to the OpenVMS Registry from a Windows NT system, you must do the following:

- On the OpenVMS system:
  - Install the Advanced Server for OpenVMS.
11.7 Connecting to the OpenVMS Registry from a Windows NT System

— Configure the Advanced Server for OpenVMS.

• On the Windows NT system:
  — Install and configure any required hardware.
  — Install and configure the Windows NT Server or Workstation software.

When you access the OpenVMS Registry database from a Windows system, you will have all the privileges granted on your Windows NT system. For example, if you are logged on to the Windows NT system as an Administrator, you will be able to read and write to all keys and values in the OpenVMS Registry. Access to OpenVMS Registry keys is based on your Windows NT user profile (username and Group membership). Connect to the OpenVMS Registry through Advanced Server for OpenVMS; use the Windows Regedt32 application to view and change keys, values, and security settings.

Caution

Be careful when you modify OpenVMS Registry database keys and values. If you damage the OpenVMS Registry database, you can affect all applications and users on the entire OpenVMS system or cluster.

11.8 OpenVMS Registry Quotas

A quota mechanism limits the size of the OpenVMS Registry database. The system assigns a quota to the root key datafile for every OpenVMS Registry file. By default, these root keys are the USERS key (REGISTRY$USERS.REG) and the LOCAL_MACHINE key (REGISTRY$LOCAL_MACHINE.REG).

The quota limits the size of the information contained within the file but does not include the size of information stored in other files, even if the files are part of the subtree.

The default quota and file-specific quotas are stored in the OpenVMS Registry under the HKEY_LOCAL_MACHINE\SYSTEM\Registry key. For more information about these keys, see Section 10.3.

11.9 OpenVMS Registry Security

A user can access (read and modify) the OpenVMS Registry directly in the following ways:

• From a Windows NT system (through a connection through Advanced Server for OpenVMS)
• Using the OpenVMS Registry system services ($REGISTRY[W])
• Using the OpenVMS Registry server management utility ($REGSCP)

For a discussion of what system privileges and right identifiers each user needs, see Section 10.5.1. For a description of how to grant the necessary system privileges and right identifiers, see Section 10.5.1.1.

You can change a key's security attributes only from a Windows NT system—you cannot change a key's security attributes from an OpenVMS system. OpenVMS does not create or manage Windows NT security attributes.
11.10 Backing Up and Restoring the OpenVMS Registry Database

The OpenVMS Registry includes a server management utility that allows you to back up and restore the entire OpenVMS Registry database to or from a file from the OpenVMS DCL prompt as long as you have the required system privileges.

For more information about backing up and restoring the OpenVMS Registry database, see Section 12.2 and the REG$CP server management utility CREATE SNAPSHOT command and the EXPORT command.

11.11 Using the OpenVMS Registry in an OpenVMS Alpha Mixed-Version Cluster

The OpenVMS Registry Server can run in an OpenVMS Alpha mixed-version cluster. That is, the OpenVMS Registry can run in a cluster that includes OpenVMS versions other than OpenVMS Version 7.2-1; but the OpenVMS Registry server must be running on the node that is running OpenVMS Version 7.2-1.

11.12 Internationalization and Unicode Support

To integrate with Windows NT, the OpenVMS Registry is Unicode compliant. For more information about Unicode, see the OpenVMS Guide to Extended File Specifications.
12.1 Managing the OpenVMS Registry Server from the Command Line

The OpenVMS Registry includes a server management utility that allows you to update and display OpenVMS Registry information from the OpenVMS DCL prompt.

The utility also allows you to back up and restore the entire OpenVMS Registry database to or from a file, as long as you have the required system privileges. For more information about backing up and restoring the OpenVMS Registry database, see Section 12.2 and the CREATE SNAPSHOT, EXPORT, and IMPORT commands in the command reference section of this chapter.

To start the OpenVMS Registry server management utility, enter one of the following commands:

$ RUN SYS$SYSTEM:REG$CP

or

$ MCR REG$CP

Note

Before you can access the OpenVMS Registry database, the OpenVMS Registry server must be running either in the cluster or on the standalone system.

Table 12–1 lists and describes OpenVMS Registry server management utility commands.

Table 12–1 OpenVMS Registry Server Management Utility Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Identifier</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE DATABASE</td>
<td>SYSPRV</td>
<td>Creates a new OpenVMS Registry database file.</td>
</tr>
<tr>
<td>CREATE KEY</td>
<td>REG$UPDATE</td>
<td>Creates one or more keys in the OpenVMS Registry database.</td>
</tr>
<tr>
<td>CREATE SNAPSHOT</td>
<td>SYSPRV</td>
<td>Makes an immediate backup of the OpenVMS Registry database files.</td>
</tr>
<tr>
<td>CREATE VALUE</td>
<td>REG$UPDATE</td>
<td>Specifies the data component for a key.</td>
</tr>
</tbody>
</table>

(continued on next page)
### Table 12–1 (Cont.) OpenVMS Registry Server Management Utility Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Identifier</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELETE KEY</td>
<td>REG$UPDATE</td>
<td>Removes one or more keys from the OpenVMS Registry database.</td>
</tr>
<tr>
<td>DELETE VALUE</td>
<td>REG$UPDATE</td>
<td>Removes one or more values from a specified key.</td>
</tr>
<tr>
<td>EXPORT</td>
<td>REG$LOOKUP</td>
<td>Exports the OpenVMS Registry to a text format.</td>
</tr>
<tr>
<td>IMPORT</td>
<td>REG$UPDATE</td>
<td>Imports a text-formatted version of a registry database to the OpenVMS Registry format.</td>
</tr>
<tr>
<td>LIST KEY</td>
<td>REG$LOOKUP</td>
<td>Displays all subkey information for a specified key.</td>
</tr>
<tr>
<td>LIST VALUE</td>
<td>REG$LOOKUP</td>
<td>Displays all values of a specified key.</td>
</tr>
<tr>
<td>MODIFY KEY</td>
<td>REG$UPDATE</td>
<td>Modifies the information of a specified key.</td>
</tr>
<tr>
<td>MODIFY VALUE</td>
<td>REG$UPDATE</td>
<td>Modifies the information of a specified value.</td>
</tr>
<tr>
<td>MODIFY TREE</td>
<td>REG$UPDATE</td>
<td>Modifies the information of a specified key and its subkeys.</td>
</tr>
<tr>
<td>SEARCH KEY</td>
<td>REG$LOOKUP</td>
<td>Displays the path name of all keys that match a specified key.</td>
</tr>
<tr>
<td>SEARCH VALUE</td>
<td>REG$LOOKUP</td>
<td>Displays the path name of all keys that match a specified value name.</td>
</tr>
<tr>
<td>SHOW COUNTERS</td>
<td>REG$PERFORMANCE</td>
<td>Displays counter information.</td>
</tr>
<tr>
<td>SHOW FILE</td>
<td>REG$PERFORMANCE</td>
<td>Displays OpenVMS Registry database file statistics.</td>
</tr>
<tr>
<td>SHOW INTERNAL</td>
<td>REG$PERFORMANCE</td>
<td>Displays internal values (used by shared libraries).</td>
</tr>
<tr>
<td>START MONITOR</td>
<td>REG$PERFORMANCE</td>
<td>Enables monitoring functions.</td>
</tr>
<tr>
<td>STOP MONITOR</td>
<td>REG$PERFORMANCE</td>
<td>Disables monitoring functions.</td>
</tr>
<tr>
<td>ZERO COUNTERS</td>
<td>REG$PERFORMANCE</td>
<td>Resets monitoring counters.</td>
</tr>
</tbody>
</table>

**Note**

A user who has the SYSPRV privilege can execute all the commands listed in Table 12–1. You must specify an OpenVMS Registry identifier only if the user does not have SYSPRV privilege.

If you grant a user the REG$UPDATE identifier, in addition to the commands listed in Table 12–1, the user can also execute the following commands:

- LIST KEY
- LIST VALUE
- SEARCH KEY
- SEARCH VALUE
12.2 Backing Up and Restoring the OpenVMS Registry Database

The REG$CP server management utility includes two commands that allow you to back up and restore an OpenVMS Registry database.

- The EXPORT command allows you to back up the OpenVMS Registry keys and values on demand in OpenVMS or Windows NT format. You can use this command to export part or all of an OpenVMS Registry database. The corresponding IMPORT command allows you to restore or import OpenVMS Registry or Windows NT Registry keys and values. For more information, see the EXPORT and IMPORT commands in the command reference section of this chapter.

- The CREATE SNAPSHOT command allows you to back up the OpenVMS Registry database files automatically on a specified schedule. By default, the REGISTRY_SERVER process creates a snapshot of the OpenVMS Registry database every 24 hours. You can change this interval by modifying the Snapshot Interval setting in the OpenVMS Registry server operations. (For more information about these operations, see Section 10.6.)

The following example shows how to modify the interval between automatic snapshots of the OpenVMS Registry database from the default of once every 24 hours to once every hour.

```
$ MCR REG$CP
REG> MODIFY VALUE HKEY_LOCAL_MACHINE\SYSTEM\REGISTRY -
_REG> /NAME="Snapshot Interval"/DATA=3600/TYPEDWORD
```

For more information, see the CREATE SNAPSHOT command in this chapter.

12.2.1 Creating a Snapshot of the OpenVMS Registry Database

Use the following procedure to create a snapshot of the OpenVMS Registry database:

1. Verify that the REGISTRY_SERVER process is running in the cluster.
2. From an account with the SYSPRV privilege, enter the following commands:

```
$ MCR REG$CP
REG> CREATE SNAPSHOT
```

The resulting snapshot consists of the following two files, located in the specified directory:

- REGISTRY$LOCAL_MACHINE.RSS
- REGISTRY$USERS.RSS

12.2.2 Restoring a Snapshot of the OpenVMS Registry Database

Use the following procedure to restore a snapshot of the OpenVMS Registry database:

1. Shut down the REGISTRY_SERVER process on all nodes in the cluster. (For information about shutting down the OpenVMS Registry, see Section 11.4.)
2. Verify that the OpenVMS Registry snapshot files are in the SYS$REGISTRY directory.

If the OpenVMS Registry snapshot files are not in the SYS$REGISTRY directory, copy the OpenVMS Registry snapshot files to the SYS$REGISTRY directory.
3. Rename the OpenVMS Registry snapshot files as follows:

   $ RENAME REGISTRY$LOCAL_MACHINE.RSS REGISTRY$LOCAL_MACHINE.REG
   $ RENAME REGISTRY$USERS.RSS REGISTRY$USERS.REG

4. Restart the **REGISTRY_SERVER** process. (For information about starting the OpenVMS Registry manually, see Section 11.3.1.)

   _____________________________ Caution _________________________________
   Any information that the system has written to the OpenVMS Registry
   database between the time of the last snapshot and this restore process
   will be lost.

   _____________________________

### 12.3 OpenVMS Registry Server Management Utility Syntax

The following command section describes each OpenVMS Registry command in alphabetical order.

   _____________________________ Note _________________________________
   In all the commands in this section, the **key-name** parameter is a string
   that specifies the full path of the key, beginning from one of following
   entry points:

   HKEY_LOCAL_MACHINE
   HKEY_USERS
   HKEY_CLASSES_ROOT

   You can also specify the strings REG$HKEY_LOCAL_MACHINE,
   REG$HKEY_USERS, and REG$HKEY_CLASSES_ROOT.

   For all server management commands, links are not followed. (For more
   information about links, see Section 10.2.1.3.)

   To make key and values names case sensitive, enclose the keys and values
   in quotation marks (for example: "value").

   _____________________________
CREATE DATABASE

Creates the basic OpenVMS Registry database files in the location specified by the SYS$REGISTRY logical. The command creates an empty database and loads the predefined keys.

If you enter this command and the database files already exist, the utility does not overwrite the existing files. The system displays a warning that the files already exist. If you want to create a new OpenVMS Registry database, you must first delete all previous versions of the database files. If you delete the OpenVMS Registry database files, you will lose all keys, subkeys, and values stored in the OpenVMS Registry.

This command requires the SYSPRV privilege.

The following table lists and describes the OpenVMS Registry database files.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REGISTRY$ROOT.DAT</td>
<td>Root of the database</td>
</tr>
<tr>
<td>REGISTRY$USERS.REG</td>
<td>HKEY_USERS tree</td>
</tr>
<tr>
<td>REGISTRY$LOCAL_MACHINE.REG</td>
<td>HKEY_LOCAL_MACHINE tree</td>
</tr>
<tr>
<td>REGISTRY$MASTER.RLG</td>
<td>The master commit log file</td>
</tr>
<tr>
<td>REGISTRY$REPLY.RLG</td>
<td>Log file that tracks modification requests to the OpenVMS Registry database</td>
</tr>
</tbody>
</table>

Format

CREATE DATABASE

Parameters

None

Qualifiers

None

Examples

REG> CREATE DATABASE

Regenerates the basic OpenVMS Registry database files if the database files are lost or deleted.
CREATE KEY

Creates one or more keys in the OpenVMS Registry database.
This command requires the SYPRV privilege or the REG$UPDATE rights identifier.

Format

CREATE KEY key-name [...]

Parameters

key-name[,...]
Specifies the name of the key to create. You can create multiple keys by separating the keys with commas.

Qualifiers

/WRITEBEHIND
/NOWRITEBEHIND (default)
Specifies that the key information must be written to disk immediately.
/NOWRITEBEHIND specifies a write-through operation.

/VOLATILE=level
/NONVOLATILE (default)
Specifies whether or not the new key is volatile. If you are running the OpenVMS Registry on a standalone OpenVMS system, volatile keys are lost when the system reboots. If you are running the OpenVMS Registry in an OpenVMS cluster, volatile keys are lost when all notes in the cluster are rebooted.
The values for level are as follows:
• NONE (same as /NONVOLATILE)
• CLUSTER

/CACHE_ACTION=value
Specifies the cache attribute for the new key. The value can be WRITEBEHIND (default) or WRITETHRU (write to disk immediately).

/CLASS_NAME=string
Specifies the class name of the key.

/SECPOLICY=policy
Defines the security policy for the key. Currently the only valid policy is NT_40.

/LINK=(TYPE=value, NAME=key-name)
Defines the key as a link to another key. The link value must be one of the following:
• SYMBOLICLINK
• NONE
To remove a link, enter the following:
/LINK=(TYPE=NONE, NAME="")
Examples

REG> CREATE KEY/CACHE_ACTION=WRITEBEHIND HKEY_USERS\GUEST, HKEY_USERS\SYSTEM

Creates the GUEST and SYSTEM keys under the HKEY_USERS entry point. The keys are created with the write-behind attribute.
CREATE SNAPSHOT

Creates a snapshot of the OpenVMS Registry database. That is, the system writes all cached OpenVMS Registry keys or values and makes a copy of the OpenVMS Registry database files.

This command requires the SYSPRV privilege.

Format

CREATE SNAPSHOT

Parameters

None

Qualifiers

/DESTINATION=file-spec
Controls where the system will write the snapshot files. By default, the system creates the snapshot in the location specified by the SYS$REGISTRY logical.

If you specify the /DESTINATION qualifier but do not provide a valid directory, the system creates the snapshot files in the directory in which you started the OpenVMS Registry server.

/VERSIONS=number
Specifies how many previous versions of the snapshot files to keep.

Examples

REG> CREATE SNAPSHOT/DESTINATION=SYS$REGISTRY/VERSION=3

Creates a snapshot of the OpenVMS Registry database in the SYS$REGISTRY directory. If more than three versions of the OpenVMS Registry database snapshot files exist, the system deletes the oldest version (the same as purge/keep=3 command).
CREATE VALUE

Specifies the data component for the specified key. If the value does not exist, the command creates the value.

This command requires the SYSPRV privilege or the REG$UPDATE rights identifier.

Format

CREATE VALUE  key-name

Parameters

key-name
Specifies the name of the key for which you will set the value.

Qualifiers

/FLAGS=flag
Specifies the data flags value. This is an application-dependent 64-bit flag specified as a decimal number or as a hexadecimal number preceded by 0x or %X.

/WRITEBEHIND
/NOWRITEBEHIND (default)
Specifies that the value must be written to disk immediately. /NOWRITEBEHIND specifies a write-through operation.

/TYPE_CODE=type
Specifies the type of the new value. The type value must be one of the following:
• SZ: a null-terminated Unicode string
• EXPAND_SZ: a string of Unicode characters
• MULTI_SZ: a concatenated array of SZ strings
• DWORD: a 32-bit number

/LINK=(TYPE=value, NAME=key-name)
Defines the key as a link to another key. The link value must be one of the following:
• SYMBOLICLINK
• NONE
OpenVMS Registry Server Management

CREATE VALUE

To remove a link, enter the following:

/LINK=(TYPE=None, NAME="")

Examples

REG> CREATE VALUE/DATA=COSMOS/TYP=SZ/NAME=COMPUTERNAME HKEY_LOCAL_MACHINE\NODE

Creates the COMPUTERNAME value for the key HKEY_LOCAL_MACHINE\NODE and sets its type to SZ and its data value to COSMOS.
DELETE KEY

Removes a specified key from the OpenVMS Registry database. The system does not delete a key if the key has subkeys.

Caution

Deleting a key results in symbolic links not being followed. This is because the system deletes the key you specified, even if it has symbolic links.

Note

The OpenVMS Registry database predefined keys are reserved keys and cannot be deleted. These keys include `HKEY_USER`, `HKEY_LOCAL_MACHINE`, and `HKEY_CLASSES_ROOT`. For a complete list, see Section 10.3.

This command requires the SYSPRV privilege or the `REG$UPDATE` rights identifier.

Format

```
DELETE KEY  key-path key-name
```

Parameters

- **key-path**
  Specifies the key path.

- **key-name**
  Specifies the name of the key to delete.

Qualifiers

- `WRITEBEHIND`
- `NOWRITEBEHIND` (default)
  Specifies that the key information must be written to disk immediately. `NOWRITEBEHIND` specifies a write-through operation.

Examples

```
REG> DELETE KEY HKEY_USERS\Node GUEST

Deletes the GUEST key from the OpenVMS Registry database.
```
DELETE VALUE

Removes a value from a specified key.

Caution

Deleting a value results in symbolic links not being followed. This is because the system deletes the value you specified, even if it has symbolic links.

This command requires the SYPRV privilege or the REG$UPDATE rights identifier.

Format

DELETE VALUE key-name value-name

Parameters

key-name
Specifies the key name whose value should be removed.

value-name
Specifies the value to remove.

Qualifiers

/WRITEBEHIND
/NOWRITEBEHIND (default)
Specifies that the information must be written to disk immediately. /NOWRITEBEHIND specifies a write-through operation.

Examples

REG> DELETE VALUE HKEY_USERS\GUEST PASSWORD

Deletes the PASSWORD value from the GUEST key.
EXPORT

Allows a user to export the OpenVMS Registry database content to a text format. You can export the entire database or specific keys and subkeys.

You can specify the exported file as a Windows NT compatible format or in an OpenVMS format. The IMPORT command supports both Windows NT 4.0 Regedit format and the OpenVMS Registry format.

This command requires the REG$LOOKUP rights identifier. If you do not have the REG$LOOKUP rights identifier, you must have the SYSPRV privilege to export keys that require the REG$LOOKUP rights identifier.

Format

```
EXPORT [DATABASE | KEY [key-name |[NO]SUBKEYS]] [/LOG] [/OUTPUT=file-name]
[/FORMAT=[NT | OPENVMS]]
```

Parameters

DATABASE
Exports the full OpenVMS Registry database.

KEY [key-name |[NO]SUBKEYS]
Exports a specific OpenVMS Registry key and, optionally, its subkeys. NOSUBKEYS is the default.

Qualifiers

/LOG
Displays the export progress to the screen.

/OUTPUT=file-name
Specifies a name for the exported file. The default output file name is REGISTRY.TXT.

/FORMAT=[NT | OPENVMS]
Specifies the format in which the system writes the database. OPENVMS is the default.

Examples

```
REG> EXPORT DATABASE/LOG/OUTPUT=TUES_VERSION.TXT/FORMAT=NT
```

The EXPORT command in this example logs the progress of the export to the screen as the system exports the entire OpenVMS Registry database to the TUES_VERSION.TXT file in Windows NT 4.0 Regedit format.
IMPORT

Allows a user to import a text-formatted file (created by the EXPORT command) into an OpenVMS Registry database.

Also allows a user to import into an OpenVMS Registry database the Windows NT data exported by Windows NT 4.0 Regedit (from the Registry menu choose the Export Registry File... option).

Conversion of Windows NT binary values

You can import Windows NT binary values (such as configuration data) into the OpenVMS Registry database, even though OpenVMS does not support the binary values. The system displays a message when importing and converting unsupported binary values.

This command requires the REG$UPDATE rights identifier. If you do not have the REG$UPDATE rights identifier, you must have the SYSPRV privilege to import keys that require the REG$LOOKUP or REG$UPDATE rights identifier.

The following table summarizes how rights identifiers and privileges affect your ability to import and export keys.

<table>
<thead>
<tr>
<th>If you have:</th>
<th>You can export from Windows NT:</th>
<th>You can import to the OpenVMS Registry:</th>
</tr>
</thead>
<tbody>
<tr>
<td>No privileges.</td>
<td>All keys created by Advanced Server for OpenVMS except HKEY_LOCAL_MACHINE\SECURITY</td>
<td>Nothing</td>
</tr>
<tr>
<td>No rights identifiers</td>
<td>All keys created by Advanced Server for OpenVMS</td>
<td>Nothing</td>
</tr>
<tr>
<td>REG$LOOKUP</td>
<td>All keys created by Advanced Server for OpenVMS</td>
<td>Nothing</td>
</tr>
<tr>
<td>REG$UPDATE</td>
<td>All keys created by Advanced Server for OpenVMS</td>
<td>All keys created by Advanced Server for OpenVMS</td>
</tr>
<tr>
<td>SYSPRV</td>
<td>All keys created by Advanced Server for OpenVMS</td>
<td>All keys created by Advanced Server for OpenVMS</td>
</tr>
</tbody>
</table>

Format

IMPORT [/LOG] [/INPUT=filename]

Parameters

None

Qualifiers

/LOG
Displays the import progress to the screen.

/INPUT=filename
Specifies a name of the file to import. The default input file name is REGISTRY.TXT.
Examples

REG> IMPORT/LOG/INPUT=TUES_VERSION.TXT

The IMPORT command in this example logs the progress of the import to the screen as the system imports the TUES_VERSION.TXT file.
LIST KEY

Displays the attributes for the specified key.

Note

Symbolic links are not followed.

This command requires the SYPRV privilege or the REG$LOOKUP rights identifier.

Format

LIST KEY  key-name

Parameters

key-name
Specifies the name of the key to list.

Qualifiers

/FULL
Displays all available information—that is, information displayed by the /LAST_WRITE, /CACHE_ACTION, /INFORMATION, /LINK_PATH, and /CLASS_NAME qualifiers.

/CACHE_ACTION=value
Specifies the cache attribute for the subkey. The value can be WRITEBEHIND (default) or WRITETHRU (write to disk immediately).

/CLASS_NAME
Displays the class name of the subkey.

/INFORMATION
Displays the information (subkey number, value number, subkey name max, and so on) about the specified key.

/LAST_WRITE
Displays the time when the subkey was last updated.

/LINK_PATH
Displays the key path to which the subkey is linked.

/OUTPUT=file-spec
Controls where the output of the command is sent. If you do not specify a file name, the system uses the default name REGISTRY.LIS.
Examples

REG> LIST KEY/FULL HKEY_USERS\GUEST

Key name: HKEY_USERS\GUEST  
Security policy: REG$K_POLICY_NT_40  
Volatile: REG$K_NONE  
Cache: REG$K_WRITEBEHIND  
Class: System Authorization  
Link Type: REG$K_NONE  
Last written: 7-AUG-1998 12:42:08.55

Key information:
Number of subkeys: 2  Number of values: 0
Max size of subkey name: 40  Max size of class name: 40
Max size of value name: 0  Max size of value data: 0

Subkey(s):
  Key name: QUOTAS  
  Security policy: REG$K_POLICY_NT_40  
  Volatile: REG$K_NONE  
  Cache: REG$K_WRITEBEHIND  
  Class: Disk quota  
  Link Type: REG$K_NONE  
  Last written: 7-AUG-1998 12:41:19.21

Key information:
Number of subkeys: 0  Number of values: 0
Max size of subkey name: 0  Max size of class name: 0
Max size of value name: 0  Max size of value data: 0

  Key name: IDENTIFIER  
  Security policy: REG$K_POLICY_NT_40  
  Volatile: REG$K-none  
  Cache: REG$K_WRITETHRU  
  Class: Disk quota  
  Link Type: REG$K_SYMBOLICLINK  
  Link Path: HKEY_LOCAL_MACHINE\SOFTWARE\IDENTIFIER\GUEST  
  Last written: 7-AUG-1998 12:42:08.55

Key information:
Number of subkeys: 0  Number of values: 0
Max size of subkey name: 0  Max size of class name: 0
Max size of value name: 0  Max size of value data: 0

The LIST KEY/FULL command in this example displays the GUEST key attributes as well as the name and attributes of the subkeys of GUEST.

Note

The Max sizes information shows the number of bytes, not characters. (Each character is 4 bytes long.)
LIST VALUE

Displays all values and value attributes of the specified key.

Note
Symbolic links are not followed.

This command requires the SYSPRV privilege or the REG$LOOKUP rights identifier.

Format

LIST VALUE  key-name

Parameters

key-name
Specifies the name of the key to enumerate.

Qualifiers

/FULL
Displays all available information—that is, information displayed by the /TYPE_CODE, /LINK_PATH, /DATA_FLAGS, and /VALUE_DATA qualifiers.

/TYPE_CODE
Display the type code of the value.

/FLAGS
Displays an ASCII representation of the data flag of the value in hexadecimal format.

/LINK_PATH
Displays the key path to which the subkey is linked.

/DATA
Displays an ASCII representation of the value in hexadecimal format.

/OUTPUT=file-spec
Controls where the output of the command is sent. If you do not specify a file name, the system uses the default name REGISTRY.LIS.

Examples

REG> LIST VALUE/TYPE_CODE/DATA HKEY_LOCAL_MACHINE\SOFTWARE\FORTRAN

Key name:  HKEY_LOCAL_MACHINE\SOFTWARE\FORTRAN
Security policy:  REG$K_POLICY_NT_40
Volatile:  REG$K_NONE
Last written:  11-AUG-1998 16:27:55.81

Value(s):

Value name:  Version
Volatile:  REG$K_NONE
Type:  REG$K_SZ
Data:  5.3-50
Value name: Date Installed
Volatile: REG$K_NONE
Type: REG$K_SZ
Data: 04-Jan-1998

The LIST VALUE/TYPE_CODE/DATA command in this example displays the FORTRAN key and its value names, types, and data.
MODIFY KEY

Modifies the attributes of the specified key.

Caution

Modifying a key results in symbolic links not being followed. This is because the system modifies the key you specified, not the key pointed to by the symbolic link.

This command requires the SYSPRV privilege or the REGUPDATE rights identifier.

Format

MODIFY KEY key-name

Parameters

key-name
Specifies the name of the key to modify.

Qualifiers

/CACHE_ACTION=value
Specifies the cache attribute for the new key. The value can be WRITEBEHIND (default) or WRITETHRU (write to disk immediately).

/CLASS_NAME=string
 Specifies the new class name of the key.

/WRITEBEHIND
/NOWRITEBEHIND (default)
Specifies that the key information must be written to disk immediately. /NOWRITEBEHIND specifies a write-through operation.

/NEW_NAME=new-key-name
Specifies the new name of the key.

/SECPOLICY=polcy
Defines the security policy for the key. Currently the only valid policy is NT_40.

/LINK=(TYPE=value, NAME=key-name)
Defines the key as a link to another key. The link value must be one of the following:

• SYMBOLICLINK
• NONE

To remove a link, enter the following:

/LINK=(TYPE=NONE, NAME="")
Examples

REG> MODIFY KEY/CACHE_ACTION=WRITEBEHIND HKEY_USERS\GUEST

Modifies the cache attribute of the GUEST key.
MODIFY VALUE

Specifies the data component for the specified value. This command modifies an existing value.

Caution

Modifying a value results in symbolic links not being followed. This is because the system modifies the value you specified, not the value pointed to by the symbolic link.

This command requires the SYSPRV privilege or the REG$UPDATE rights identifier.

Format

MODIFY VALUE /NAME=string  key-name

Parameters

key-name

Specifies the name of the key for which to set the value.

Qualifiers

/FLAGS=flag

Specifies the data flags value. This is an application-dependent 64-bit flag specified as a decimal number or as a hexadecimal number preceded by 0x or %X.

/WRITEBEHIND

/NOWRITEBEHIND (default)

Specifies that the value information must be written to disk immediately. /NOWRITEBEHIND specifies a write-through operation.

/DATA=value

Specifies the data for the value. The value can be:

- A string (for example, /DATA=COSMOS)
- An array of strings separated by a comma and enclosed in parentheses (for example, /DATA=(COSMOS,Noidea)
- A longword in octal (%O), decimal, or hexadecimal (%X) format (for example, /DATA=%X1A0FCB or /DATA=1234)

/NAME=string

Specifies the name of the value.

/TYPES_CODE=type

Specifies the type of the new value. The type value must be one of the following:

- SZ: a null-terminated Unicode string
- EXPAND_SZ: a string of Unicode characters
- MULTI_SZ: a concatenated array of SZ strings
- DWORD: a 32-bit number
/LINK=(TYPE=value, NAME=key-name)
Defines the key as a link to another key. The link value must be one of the following:

- SYMBOLICLINK
- NONE

To remove a link, enter the following:

/LINK=(TYPE=NONE, NAME="")

Examples

REG> MODIFY VALUE/DATA=COSMOS/TYPE=SZ/NAME=COMPUTERNAME HKEY_LOCAL_MACHINE\NODE

Creates COMPUTERNAME value for the key HKEY_LOCAL_MACHINE\NODE, and sets its type code to SZ and its data value to COSMOS.
MODIFY TREE

Modifies the information for the specified key and its subkeys.

_________________________ Caution ____________________________

Modifying a tree results in symbolic links not being followed. This is because the key and subkeys you specify are modified, not the key pointed to by the symbolic link.

This command requires the SYSPRV privilege or the REGUPDATE rights identifier.

Format

MODIFY TREE  key-name

Parameters

*key-name*

Specifies the name of key to modify.

Qualifiers

/CACHE_ACTION=value

Specifies the cache attribute for the key and its subkeys. The value can be WRITEBEHIND (default) or WRITETHRU (write to disk immediately).

/CLASS_NAME=string

Specifies the new class name for the given key and all its subkeys.

/WRITEBEHIND/

/NOWRITEBEHIND (default)

Specifies that the key information must be written to disk immediately. /NOWRITEBEHIND specifies a write-through operation.

/SECPOLICY=policy

Defines the security policy for the key. Currently the only valid policy is NT_40.

Examples

REG> MODIFY TREE/CACHE_ACTION=WRITEBEHIND HKEY_USERS\GUEST

Modifies the cache attribute of the GUEST key and all its subkeys.
SEARCH KEY

Displays the path name of all the keys that match the specified key. This command requires the SYSPRV privilege or the REG$LOOKUP rights identifier.

Format

SEARCH KEY key-search

Parameters

key-search
Specifies the key name for which to search.

Qualifiers

/OUTPUT=file-spec
Controls where the output of the command is sent. If you do not specify a file name, the system uses the default name REGISTRY.LIS.

Examples

REG> SEARCH KEY HKEY_LOCAL_MACHINE\...\NODE HARDWARE\CLUSTER\NODE HARDWARE\LOCAL\NODE NODE

Displays all the key paths that match the HKEY_LOCAL_MACHINE\...\NODE selection. The ellipsis (...) wildcard specifies that there can be any number of subkeys between the HKEY_LOCAL_MACHINE entry point and the NODE subkey. Note that the search is not case sensitive.
SEARCH VALUE

Displays the path name of all the values that match the specified value name. This command requires the SYSPRV privilege or the REG$LOOKUP rights identifier.

Format

SEARCH VALUE  key-name value-name

Parameters

- **key-name**
  Specifies the name of the key path to search.

- **value-name**
  Specifies the value name for which to search.

Qualifiers

- **/OUTPUT=file-spec**
  Controls where the output of the command is sent. If you do not specify a file name, the system uses the default name **REGISTRY.LIS**.

Examples

```
REG> SEARCH VALUE HKEY_LOCAL_MACHINE\...\*AM%
HARDWARE\CLUSTER\Name
HARDWARE\CLUSTER\NODE\Name
HARDWARE\LOCAL\NODE\Name
NODE\COMPUTERNAME
```

Displays all the value names that match the `HKEY_LOCAL_MACHINE\...\*am%` selection. The ellipsis (...) wildcard specifies that there can be any number of subkeys between the `HKEY_LOCAL_MACHINE` entry point and the `*am%` value name. Note that the search is not case sensitive.
SHOW

Displays OpenVMS Registry server internal statistics and information.

- **SHOW COUNTERS**
  Displays monitoring information from the OpenVMS Registry server.

- **SHOW FILE**
  Displays status information on files loaded into the OpenVMS Registry server.

This command requires the SYSPRV privilege or the REG$PERFORMANCE rights identifier.

**Format**

SHOW COUNTERS/FILE [name]
SHOW FILE [name]

**Parameters**

*name*
Identifies the file (used with the /FILE qualifier only).

**Qualifiers**

/FILE
Displays counters for the specified file or for all files.

/PERFORMANCE
Displays performance counters.

/OUTPUT=file-spec
Controls where the output of the command is sent. If you do not specify a file name, the system uses the default name REGISTRY.LIS.

**Examples**

REG> SHOW COUNTERS/FILE

Displays monitoring information from the OpenVMS Registry server.
START MONITORING

Starts a monitoring component within the OpenVMS Registry server.

This command requires the SYSPRV privilege or the REG$PERFORMANCE rights identifier.

Format

START MONITORING/FILE [name]
START MONITORING/PERFORMANCE

Parameters

name
Identifies the file (used with the /FILE qualifier only).

Qualifiers

/FILE
Start gathering counters for the specified file or for all files.

/PERFORMANCE
Start gathering performance counters.

Examples

REG> START MONITORING/PERFORMANCE

Enables a monitoring component of the OpenVMS Registry.
**STOP**

Stops a monitoring component within the OpenVMS Registry server. This command is used to stop a monitoring component within the OpenVMS Registry server.

This command requires the SYSPRV privilege or the REG$PERFORMANCE rights identifier.

**Format**

```
STOP MONITORING/FILE [name]
STOP MONITORING/PERFORMANCE
```

**Parameters**

- **name**
  Identifies the file (used with the /FILE qualifier only).

**Qualifiers**

- **/FILE**
  Stop gathering counters for the specified file or for all files.

- **/PERFORMANCE**
  Stop gathering performance counters.

**Examples**

```
REG> STOP MONITORING/PERFORMANCE
```

Disables a monitoring component of the OpenVMS Registry.
Zero Counters

Initializes counters within the OpenVMS Registry server. This command requires the SYSPRV privilege or the REG$PERFORMANCE rights identifier.

Format

ZERO COUNTERS/FILE  [name]
ZERO COUNTERS/PERFORMANCE

Parameters

name
Identifies the file (used with the /FILE qualifier only).

Qualifiers

/FILE
Initializes the file counters for the specified file or for all files.

/PERFORMANCE
Initializes all performance counters.

Examples

REG> ZERO COUNTERS/PERFORMANCE
Resets the performance counters.
This chapter lists and describes the OpenVMS Registry $REGISTRY and $REGISTRYW system services.
The $REGISTRY and $REGISTRYW system services are the interface to the OpenVMS Registry database server. The $REGISTRY service allows you to query, update, and set keys, subkeys, and values in the OpenVMS Registry database.

The $REGISTRY service supports both asynchronous and synchronous operations. For asynchronous completion, use the Registry ($REGISTRY) system service. For synchronous completion, use the Registry and Wait ($REGISTRYW) system service. The $REGISTRYW system service is identical to the $REGISTRY system service, except that $REGISTRYW returns to the caller after the system completes the requested operation. For additional information about system service completion, see the Synchronize ($SYNCH) system service.

This system service is 64-bit compatible.

Format

SYS$REGISTRY  [efn], func, 0, itmlst, [iosb or iosa_64], [astadr or astadr_64], [astprm or astprm_64]
SYS$REGISTRYW [efn], func, 0, itmlst, [iosb or iosa_64], [astadr or astadr_64], [astprm or astprm_64]

Arguments

efn
OpenVMS usage: ef_number
type: longword (unsigned)
access: read only
mechanism: by value

Number of the event flag to be used by $REGISTRY. If you do not specify the event flag, the system defaults to event flag 0. The event flag is initially cleared by $REGISTRY and then set when the operation completes.

func
OpenVMS usage: function_code
type: longword (unsigned)
access: read only
mechanism: by value

Function code specifying the action that $REGISTRY is to perform. The func argument is a longword containing this function code. The function code can contain function modifiers. For more information on function modifiers, see the Function Modifiers section in this chapter.

A single call to $REGISTRY can specify only one function code. All function codes require additional information to be passed in the call with the itmlst argument.

itmlst
OpenVMS usage: item_list3 or item_list_64b
type: longword (unsigned)
access: read only
mechanism: by reference

Item list supplying information that the system will use to perform the function specified by the func argument. The itmlst argument is the address of the item
list. The item list consists of one or more sets of item descriptors. Each descriptor is either an item-list-3 or item-list-64b format.

Some function codes allow you specify multiple operations in a single call. In this case, you must place the REG$SEP item code between each set of item codes. Each request, separated by a REG$SEP item code, can contain the item codes in any order.

You can specify item codes as either input or output parameters. Input parameters modify functions, set context, or describe the information to be returned. Output parameters return the requested information. For item-list-3 lists, you must terminate the list with a longword of 0. For item-list-64b lists, you must terminate the list with a quadword of 0.

Figure 13–1 shows the structure of an item-list-3 descriptor.

Figure 13–1 Item-list-3 Structure

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Buffer length</td>
<td>A word that specifies the length of the buffer. The buffer either supplies information to be used by $REGISTRY, or receives information from $REGISTRY. The required length of the buffer varies, depending on the item code specified. Each item code description specifies the required length.</td>
</tr>
</tbody>
</table>

(continued on next page)
Table 13–1 (Cont.) Item Descriptor Fields

<table>
<thead>
<tr>
<th>Descriptor Field</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Item code</td>
<td>A word containing a symbolic code that describes the type of information currently in the buffer or that is returned in the buffer. The buffer address field points to the location of the buffer.</td>
</tr>
<tr>
<td>Buffer address</td>
<td>A longword that contains the address of the buffer that specifies or receives the information.</td>
</tr>
<tr>
<td>Return length address</td>
<td>A longword that contains the address of a word that specifies the actual length in bytes of the information returned by $REGISTRY. The information resides in a buffer identified by the buffer address field. The field applies to output item list entries only, and must be 0 (zero) for input entries. If the return length address is 0, it is ignored.</td>
</tr>
</tbody>
</table>

**iosb or iosa_64**

OpenVMS usage: status_block

type: buffer

access: write only

mechanism: by reference

Status block to receive the final completion status and information of the $REGISTRY operation. If multiple operations are requested for a function code, the value returned in **iosb** is either SS$_NORMAL_ or SS$_REGERROR_. A more specific return status for each operation is returned in the **REG$_RETURNSTATUS_** item code (if specified). The **iosb** argument is the address of the $REGISTRY status block.

```
+--------+--------+
|   31   |   15   |
|       |       |
| Status | Reserved |
```

When $REGISTRY begins execution, it clears the quadword I/O status block if you specify the **iosb** argument.

Although the **iosb** argument is optional, Compaq strongly recommends that you specify it for the following reasons:

- If you are using an event flag to signal the completion of the service, you can test the I/O status block for a condition value to be sure that the event flag was not set by an event other than service completion.
- If you are using the **$SYNCH** system service to synchronize completion of the service, the I/O status block is a required argument for **$SYNCH**.

The condition value returned in R0 and the condition value returned in the I/O status block provide information about different aspects of the call to the $REGISTRY service. The condition value returned in R0 provides information about the success or failure of the service call itself; the condition value returned in the I/O status block provides information about the success or failure of the service operation.
To assess the success or failure of the call to $REGISTRY accurately, you must first check the condition value returned in R0. If R0 contains a successful value, you must check the condition value in the I/O status block.

Table 13–2 defines the item descriptor fields.

Table 13–2  Descriptor Fields

<table>
<thead>
<tr>
<th>Descriptor Field</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status</td>
<td>A longword specifying the final status of the $REGISTRY service. If you request multiple operations for a function code, the system returns either SS$_NORMAL or SS$_REGERROR to iosb. This field is set to 0 (zero) when the operation begins.</td>
</tr>
<tr>
<td>Reserved</td>
<td>A reserved longword.</td>
</tr>
</tbody>
</table>

astadr or astadr_64
OpenVMS usage: ast_procedure
type: procedure value
access: call without stack unwinding
mechanism: by reference

AST service routine to be executed when $REGISTRY completes. The astadr argument is the address of this routine. If you specify astadr, the AST routine executes at the same access mode as the caller of the $REGISTRY service.

If the $REGISTRY service is not called successfully (that is, if it returns an error immediately), the AST routine is not executed.

astprm or astprm_64
OpenVMS usage: user_arg
type: longword (unsigned)
access: read only
mechanism: by value

AST parameter to be passed to the AST service routine specified by the astadr argument. The astprm argument specifies this longword parameter.

Description

The $REGISTRY service provides the means to create, delete and modify registry keys, key values, and key attributes.

The $REGISTRY service uses process P1 space to store handles to keys. The $REGISTRY service must be called at IPL 0, and requires system dynamic memory to deliver AST requests.

Related Services

Unknown thread request code

REG$_VALUEEXIST
Value already exists

REG$_VOLMISMATCH
Cannot create nonvolatile subkey for a volatile key

Function Codes

Table 13–3 provides a summary of valid function codes, a brief description of their function, and the OpenVMS Registry rights identifier required to perform the function. You can find a detailed description of each item code in the Item Codes section of this chapter.

The OpenVMS Registry identifier is required only if you do not provide a valid NT access token and you do not have the SYSPRV privilege. If you have a granted REG$UPDATE identifier, you can perform all the functions in Table 13–3.

Table 13–3 Valid Function Codes

</tbody>
</table>
OpenVMS Registry System Services
$REGISTRY and $REGISTRYW

**REG$FC_CLOSE_KEY**
This request releases the open resources of the specified key. If REG$KEYID indicates a predefined key, the system ignores the action and returns success.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>

**REG$FC_CREATE_KEY**
If the key does not exist, this request creates a new subkey under the key specified by REG$KEYID. If the key does exist, the system does not modify it.

If you specify the REG$KEYRESULT item code, the system opens the specified subkey.

The system returns the result in the REG$DISPOSITION item code buffer.

Using this function code, you can group multiple requests into a single call to the $REGISTRY service. To use the multiple-request feature, you must use the REG$SEPARATOR item code to indicate the end of the set of item codes for the current request and that there is another request to process.

To set a value for a key, call the $REGISTRY service with the REG$FC_SET_VALUE function code.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$CACHEACTION</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$CLASSNAME</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$DISPOSITION</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$KEYFLAGS</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$KEYRESULT</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$LINKPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$LINKTYPE</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$SECACCESS</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$SECURITYPOLICY</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$SEPARATOR</td>
<td>No</td>
<td>n/a</td>
</tr>
<tr>
<td>REG$SUBKEYNAME</td>
<td>Yes</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$VOLATILE</td>
<td>No</td>
<td>Input</td>
</tr>
</tbody>
</table>

If you specify the REG$LINKPATH item code, it must point to a key path already defined in the OpenVMS Registry; otherwise the system returns the REG$INVALIDPATH error.
**Note**

If you do not specify the `REG$CACHEACTION` item code, the new key is created with the same cache action value as the parent key. The same rule applies to the `REG$VOLATILE` and `REG$SECURITYPOLICY` item codes.

---

**REG$FC_DELETE_KEY**

This request removes the specified subkey and its values from the OpenVMS Registry database. If the specified key has subkeys, the key is not deleted. You must delete the subkeys first.

Using this function code, you can group multiple requests into a single call to the `$REGISTRY` service. If you use this multiple-request feature, use the `REG$SEPARATOR` item code to indicate the end of the set of item codes for the current request and that there is another request to process.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>REG$KEYID</code></td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td><code>REG$KEYPATH</code></td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td><code>REG$RETURNSTATUS</code></td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td><code>REG$SEPARATOR</code></td>
<td>No</td>
<td>n/a</td>
</tr>
<tr>
<td><code>REG$SUBKEYNAME</code></td>
<td>Yes</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
</tbody>
</table>

---

**REG$FC_DELETE_VALUE**

This request deletes the specified value from the key.

Using this function code, you can group multiple requests into a single call to the `$REGISTRY` service. If you use this multiple-request feature, use the `REG$SEPARATOR` item code to indicate the end of the set of item codes for the current request and that there is another request to process.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>REG$KEYID</code></td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td><code>REG$KEYPATH</code></td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td><code>REG$RETURNSTATUS</code></td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td><code>REG$SEPARATOR</code></td>
<td>No</td>
<td>n/a</td>
</tr>
<tr>
<td><code>REG$VALUENAME</code></td>
<td>Yes</td>
<td>Input</td>
</tr>
</tbody>
</table>

---

**REG$FC_ENUM_KEY**

This request retrieves information about one subkey of the key. You identify the subkey in the `REG$SUBKEYINDEX` item code. To enumerate all the key's subkeys, the application must call the `$REGISTRY` service repeatedly using the `REG$FC_ENUM_KEY` function code. Begin with a `REG$SUBKEYINDEX` of zero, then increment the count until the request returns a `REG$NOMOREITEMS` error.
Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_CACHEACTION</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_CLASSNAME</td>
<td>No</td>
<td>Output (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_KEYFLAGS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LASTWRITE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_LINKCOUNT</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_LINKPATH</td>
<td>No</td>
<td>Output (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LINKTYPE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SECURITYPOLICY</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SUBKEYINDEX</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_SUBKEYNAME</td>
<td>No</td>
<td>Output (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_VOLATILE</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>

**REG$FC_ENUM_VALUE**

This request retrieves information about a value of the specified key identifier. The value to retrieve is identified in the REG$_VALUEINDEX item code.

To enumerate all a key’s values, the application must call the $REGISTRY service repeatedly using the REG$FC_ENUM_VALUE function code. Begin with a REG$_VALUEINDEX of zero, then increment the count until the request returns a REG$_NOMOREITEMS error.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_DATAFLAGS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_DATATYPE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VALUEDATA</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VALUEINDEX</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_VALUENAME</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VOLATILE</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>
REG$FC_FLUSH_KEY
This request writes all the information about a specified key to disk. This request returns only after the operation is complete and all attributes of the key have been written to the OpenVMS Registry database.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>

REG$FC_MODIFY_KEY
This request modifies a specified key's attributes.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_CACHEACTION</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_CLASSNAME</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_KEYFLAGS</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LINKPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LINKTYPE</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_NEWNAME</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SECURITYPOLICY</td>
<td>No</td>
<td>Input</td>
</tr>
</tbody>
</table>

To remove the link from the specified key, enter a REG$_LINKPATH item code with an address of zero. You cannot add a link to a key that has either values or subkeys (or both).

REG$FC_MODIFY_TREE_KEY
This request modifies a specified key and all its subkey attributes. No link will be followed or modified.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_CACHEACTION</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_CLASSNAME</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
</tbody>
</table>
### REG$FC_NOTIFY_CHANGE_KEY_VALUE

This request notifies the calling process when a specified key or any of its subkeys has changed. That is, the requested function waits for the specified condition before returning.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$FLAGSUBKEY</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$NOTIFYFILTER</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>

### REG$FC_OPEN_KEY

This request opens the specified key. If you do not specify a subkey, the system opens the key specified in REG$KEYID. If REG$KEYID specifies a key other than a predefined key, the system opens the key again (duplicates the key).

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$KEYRESULT</td>
<td>Yes</td>
<td>Output</td>
</tr>
<tr>
<td>REG$KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$SECACCESS</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$SUBKEYNAME</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
</tbody>
</table>

### REG$FC_QUERY_KEY

This request retrieves attributes about a specified key.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$CACHEACTION</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>Item Code</td>
<td>Required</td>
<td>Parameter Type</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------</td>
<td>-----------------------------------------------------</td>
</tr>
<tr>
<td>REG$_CLASSNAME</td>
<td>No</td>
<td>Output (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_CLASSNAMEMAX</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_KEYFLAGS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LASTWRITE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_LINKCOUNT</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_LINKPATH</td>
<td>No</td>
<td>Output (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LINKTYPE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SECURITYPOLICY</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SUBKEYNAMEMAX</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SUBKEYSNUMBER</td>
<td>Yes</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VALUEDATAMAX</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VALUENAMEMAX</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VALUENUMBER</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VOLATILE</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>

**REG$FC_QUERY_VALUE**

This request retrieves the type, data flags, and data for the specified value name.

Using this function code, you can group multiple requests into a single call to the $REGISTRY service. If you use this multiple-request feature, use the REG$SEPARATOR item code to indicate the end of the set of item codes for the current request and that there is another request to process.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_DATAFLAGS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_DATATYPE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_LINKCOUNT</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_LINKPATH</td>
<td>No</td>
<td>Output (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_LINKTYPE</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_SEPARATOR</td>
<td>No</td>
<td>n/a</td>
</tr>
<tr>
<td>REG$_VALUEDATA</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>
REG$FC_SEARCH_TREE_DATA
This request scans a specified key and all its descendants for a match with a specified set of data information. The set of data information can be either the REG$_DATAFLAGS item code, or the pair REG$_DATATYPE and REG$_VALUEDATA item codes, or all three item codes.

The REG$_FLAGOPCODE item code specifies how the REG$_DATAFLAGS item code should be matched against the database. (See the item codes description for more information about the REG$_FLAGOPCODE item code.)

Every time the system finds a match, it appends the path name relative to the specified key to the REG$_PATHBUFFER item code. A Unicode null character is used to separate the value path names.

If the buffer supplied by the application is not big enough to hold all the value path names found, the system returns the SS$_BUFFEROVF error message in the iosb argument, and the length required to complete the operation successfully is returned in the REG$_REQLENGTH item (if specified).

Use the ellipsis (...) wildcard to match zero or more subkeys in the REG$_KEYPATH item code. (For example, Hardware\...\disks finds all the paths that start with the Hardware subkey and end with the disk subkey, with zero or more subkeys in between.) Use the asterisk (*) wildcard to match an entire subkey or a portion of a subkey in the REG$_KEYPATH item code. Use the percent (%) wildcard to match one character in a key name in the REG$_KEYPATH item code.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_DATAFLAGS</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_DATATYPE</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_FLAGOPCODE</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_PATHBUFFER</td>
<td>Yes</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_REQLENGTH</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_VALUEDATA</td>
<td>No</td>
<td>Input</td>
</tr>
</tbody>
</table>

REG$FC_SEARCH_TREE_KEY
This request scans a specified key and all its descendants for a specified key path.

For this function code, a valid key path is a Unicode string that can include the ellipsis (...), asterisk (*), or percent (%) wildcard character, but that cannot start with the backslash character (\ ).
Use the ellipsis (...) wildcard to match zero or more subkeys in the REG$_KEYPATH item code. (For example, Hardware\...\disks finds all the paths that start with the Hardware subkey and end with the disk subkey, with zero or more subkeys in between.) Use the asterisk (*) wildcard to match an entire subkey or a portion of a subkey in the REG$_KEYPATH item code. Use the percent (%) wildcard to match one character in a key name in the REG$_KEYPATH item code.

An example of a valid key path is as follows:

    hardware\system\*\disk%%

Every time the system finds a match, the system appends its path name relative to the specified key identifier to the REG$_PATHBUFFER item code. A Unicode null character (4 bytes) separates the subkey path names.

If the buffer supplied by the application is not big enough to contain all the subkey path names found, the system returns the SS$_BUFFEROVF error message in the iosb argument, and the system returns the required length to complete the operation successfully in the REG$_REQLENGTH item (if specified).

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_KEYID</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_KEYPATH</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_PATHBUFFER</td>
<td>Yes</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_REQLENGTH</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_RETURNSTATUS</td>
<td>No</td>
<td>Output</td>
</tr>
</tbody>
</table>

REG$FC_SEARCH_TREE_VALUE
This request scans a specified key and all its descendants for a specified value name.

For this function code a valid key name is a Unicode string that can include the ellipsis (...), asterisk (*), or percent (%) wildcard character, but cannot start with the backslash character (\).

Use the ellipsis (...) wildcard to match zero or more subkeys in the REG$_KEYPATH item code. (For example, Hardware\...\disks finds all the paths that start with the Hardware subkey and end with the disk subkey, with zero or more subkeys in between.) Use the asterisk (*) wildcard to match an entire subkey or a portion of a subkey in the REG$_KEYPATH item code. Use the percent (%) wildcard to match one character in a key name in the REG$_KEYPATH item code.

An example of a valid key path is as follows:

    hardware\system\...

For this function code, a valid name is a Unicode string that can include the asterisk (*) and percent (%) wildcard characters.

Every time the system finds a match, the system appends its path name relative to the specified key identifier to the REG$_PATHBUFFER item code. A Unicode null character (4 bytes) separates the subkey path names.
If the buffer supplied by the application is not big enough to contain all the subkey path names found, the system returns the SS$$_{BUFFEROVF}$$ error message in the $$iosb$$ argument, and the system returns the required length to complete the operation successfully in the REG$_{REQLENGTH}$$ item (if specified).

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_{KEYPATH}</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_{KEYID}</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_{PATHBUFFER}</td>
<td>Yes</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_{REQLENGTH}</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_{RETURNSTATUS}</td>
<td>No</td>
<td>Output</td>
</tr>
<tr>
<td>REG$_{VALUENAME}</td>
<td>Yes</td>
<td>Input</td>
</tr>
</tbody>
</table>

**REG$FC_SET_VALUE**

This request sets value and type information for a specified key.

Using this function code, you can group multiple requests into a single call to the $REGISTRY service. If you use this multiple-request feature, use the REG$_{SEPARATOR}$$ item code to indicate the end of the set of item codes for the current request and that there is another request to process.

When a value is set to a link, the system validates the link unless you specify the REG$_{M_IGNORE_LINKS}$$ function code modifier.

Specify the item codes as follows:

<table>
<thead>
<tr>
<th>Item Code</th>
<th>Required</th>
<th>Parameter Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_{DATAFLAGS}</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_{DATATYPE}</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_{KEYID}</td>
<td>Yes</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_{KEYPATH}</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_{LINKPATH}</td>
<td>No</td>
<td>Input (Pointer to Unicode string. Unicode character is 4 bytes long.)</td>
</tr>
<tr>
<td>REG$_{LINKTYPE}</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_{RETURNSTATUS}</td>
<td>No</td>
<td>n/a</td>
</tr>
<tr>
<td>REG$_{SEPARATOR}</td>
<td>No</td>
<td>n/a</td>
</tr>
<tr>
<td>REG$_{VALUEDATA}</td>
<td>No</td>
<td>Input</td>
</tr>
<tr>
<td>REG$_{VALUENAME}</td>
<td>No</td>
<td>Input</td>
</tr>
</tbody>
</table>

**Item Codes**

Table 13–4 provides a summary of item codes that are valid as an item descriptor in the itmlst argument. The table lists the item codes, input/output usage, and data types. Complete descriptions of each item code are provided in the sections that follow this table.
<table>
<thead>
<tr>
<th>Item Code</th>
<th>Input/Output</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_CACHEACTION</td>

</tbody>
</table>

### REG$_CACHEACTION

The `REG$_CACHEACTION` item code is an input item code. It is a longword flag that specifies whether the information on a specified object should be written to disk immediately. It takes one of the following values:

<table>
<thead>
<tr>
<th>Cache Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_WRITEBEHIND</td>
<td>Write information about the specified object written to disk at a later time (default).</td>
</tr>
<tr>
<td>REG$K_WRITETHRU</td>
<td>Write information about the specified object to disk immediately.</td>
</tr>
</tbody>
</table>

---

**Note**

If you do not specify this item code, the value or key inherits its value from the parent object. By default, the entry points (`REG$_HKEY_CLASSES_ROOT`, `REG$_HKEY_LOCAL_MACHINE`, and `REG$_HKEY_USERS`) are set with a value equal to that of `REG$K_WRITEBEHIND`.

---

### REG$_CLASSNAME

The `REG$_CLASSNAME` item code is, depending on the function code, either an input or output item code. The class name is an information field for a key. The type of an object is an example of a class name. It can be composed of any string of Unicode characters. A Unicode character is 4 bytes long.

### REG$_CLASSNAMEMAX

The `REG$_CLASSNAMEMAX` item code is an output item code. It receives the length, in bytes, of the longest string specifying a subkey class name.

### REG$_DATAFLAGS

Depending on the function code, the `REG$_DATAFLAGS` item code is either an input or output item code. It is a 64-bit application-dependent value data flag.

### REG$_DATATYPE

Depending on the function code, the `REG$_DATATYPE` item code is either an input or output item code. It is a longword that either specifies the type of information...
to be stored as a value data or receives the type of information of a specified value data component. It takes one of the following values:

<table>
<thead>
<tr>
<th>Type code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_BINARY</td>
<td>Binary data</td>
</tr>
<tr>
<td>REG$K_DWORD</td>
<td>A 32-bit number</td>
</tr>
<tr>
<td>REG$K_EXPAND_SZ</td>
<td>A string of Unicode characters</td>
</tr>
<tr>
<td>REG$K_MULTI_SZ</td>
<td>A concatenated array of REG$K_SZ strings</td>
</tr>
<tr>
<td>REG$K_NONE</td>
<td>No defined value type (default)</td>
</tr>
<tr>
<td>REG$K_QWORD</td>
<td>A 64-bit number</td>
</tr>
<tr>
<td>REG$K_SZ</td>
<td>A null-terminated Unicode string</td>
</tr>
</tbody>
</table>

--- The difference between REG$K_EXPAND_SZ and REG$K_SZ ---

A string is a set of characters usually in human-readable form. Many value entries in the OpenVMS Registry are written using a string (REG_SZ) or an expandable string (REG_EXPAND_SZ) format. An expandable string is usually human-readable text, but it can also include a variable that will be replaced when the string is called by an application.

For example, on a Windows NT system, in the value entry %SystemRoot%\System32\Bootok.exe, %SystemRoot% is the expandable portion of the variable. This part is replaced with the actual location of the directory that contains the Windows NT system files.

--- REG$DISPOSITION ---

The REG$DISPOSITION item code is an output item code. It is a longword and takes one of the following values:

<table>
<thead>
<tr>
<th>Disposition value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_CREATENEWKEY</td>
<td>The key did not exist and was created.</td>
</tr>
<tr>
<td>REG$K_OPENEXISTINGKEY</td>
<td>The key existed and was opened.</td>
</tr>
</tbody>
</table>

--- REG$FLAGOPCODE ---

The REG$FLAGOPCODE item code is an input item code. It is a longword flag that indicates how the REG$DATAFLAGS input item code should be matched against the data flags field in the OpenVMS Registry database. It takes one of the following values:

<table>
<thead>
<tr>
<th>Operator code options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_ANY</td>
<td>The data field in the OpenVMS Registry database must contain at least one of the flags in the REG$DATAFLAGS input item code.</td>
</tr>
<tr>
<td>REG$K_EXACTMATCH</td>
<td>The REG$DATAFLAGS input item code must match exactly the data flags field in the OpenVMS Registry database.</td>
</tr>
<tr>
<td>Operator code options</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>REG$K_EXCLUDE</td>
<td>The data flags field in the OpenVMS Registry database must not contain the flags in the REG$_DATAFLAGS input item code.</td>
</tr>
<tr>
<td>REG$K_INCLUDE</td>
<td>The data flags field in the OpenVMS Registry database must contain, at a minimum, the flags in the REG$_DATAFLAGS input item code.</td>
</tr>
<tr>
<td>REG$K_NOTANY</td>
<td>The data field in the OpenVMS Registry database must not contain any of the flags in the REG$_DATAFLAGS input item code.</td>
</tr>
</tbody>
</table>

**REG$_FLAGSUBKEY**
The REG$_FLAGSUBKEY item code is an input item code. It is a longword Boolean field that indicates the following:

- If set to 1, report changes in a specified key and any of its subkeys.
- If set to 0, report changes to a specified key only.

**REG$_KEYID**
The REG$_KEYID item code is an input item code. It is a longword that contains the key identifier.

**REG$_KEYRESULT**
The REG$_KEYRESULT item code is an output item code. It is a longword that receives a key identifier. The key identifier can be passed to other Registry calls using the REG$_KEYID item code.

**REG$_KEYPATH**
The REG$_KEYPATH item code is an input item code. It is a string of Unicode characters that specifies a key path. A Unicode character is 4 bytes long.

**REG$_LASTWRITE**
The REG$_LASTWRITE item code is an output item code. It is a quadword representation of absolute time that receives the time a specified key was last written to (including changes to its values).

**REG$_LINKCOUNT**
The REG$_LINKCOUNT item code is an output item code. It is longword count of the number of symbolic links that refer to the item.

**REG$_LINKPATH**
The REG$_LINKPATH item code is, depending on the function code, either an input or an output item code. It is a string of Unicode characters that specifies the key path to which a specified key is linked. A Unicode character is 4 bytes long.

**REG$_LINKTYPE**
The REG$_LINKTYPE item code is, depending on the function code, either an input or an output item code. It is longword type that indicates the link type.

<table>
<thead>
<tr>
<th>Link Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_NONE</td>
<td>No link (default)</td>
</tr>
<tr>
<td>Link Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>REG$_K_SYMBOLICLINK</td>
<td>Symbolic (logical) link</td>
</tr>
</tbody>
</table>

**REG$_NEWNAME**

The `REG$_NEWNAME` item code is a string of Unicode characters that specifies the new name of the key.

**REG$_NOTIFYFILTER**

The `REG$_NOTIFYFILTER` item code is an input item code. It is a longword mask that specifies which changes to the specified key and its subkeys and values to report. It takes any combination of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$_M_CHANGEATTRIBUTES</td>
<td>An attribute change of the specified key or its subkeys.</td>
</tr>
<tr>
<td>REG$_M_CHANGELASTSET</td>
<td>Changes to the last write time of the specified key or its subkeys.</td>
</tr>
<tr>
<td>REG$_M_CHANGEFILENAME</td>
<td>A key name change, including creation and deletion, of the specified key or its subkeys.</td>
</tr>
</tbody>
</table>

**Note**

The system report changes to subkeys of the specified key only if the `REG$_FLAGSUBKEY` item code is set to 1.

**REG$_PATHBUFFER**

The `REG$_PATHBUFFER` item code is an output item code. It is a buffer that receives a set of either key paths or value paths, separated by a null Unicode character (4 bytes long). (The third longword of the item descriptor contains the number of bytes written to the buffer.)

**REG$_REQLENGTH**

The `REG$_REQLENGTH` item code is an output item code. It is a longword that receives the required buffer size (in bytes) to complete the operation successfully.

**REG$_RETURNSTATUS**

The `REG$_RETURNSTATUS` item code is an output item code. It is a longword that receives the final completion status for a specified operation. For more information, see the **Condition Values Returned** section of this chapter.

**REG$_SECACCESS**

The `REG$_SECACCESS` item code is an input item code. It is a longword mask that specifies the desired security access for the new key. It takes any combination of the following values:
### OpenVMS Registry System Services

#### $REGISTRY and $REGISTRYW

<table>
<thead>
<tr>
<th>Security access mask</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$M_ALLACCESS</td>
<td>A combination of the following access values:</td>
</tr>
<tr>
<td></td>
<td>REG$K_CREATELINK</td>
</tr>
<tr>
<td></td>
<td>REG$K_CREATESUBKEY</td>
</tr>
<tr>
<td></td>
<td>REG$K_ENUMSUBKEYS</td>
</tr>
<tr>
<td></td>
<td>REG$K_NOTIFY</td>
</tr>
<tr>
<td></td>
<td>REG$K_QUERYVALUE</td>
</tr>
<tr>
<td></td>
<td>REG$K_SETVALUE</td>
</tr>
<tr>
<td>REG$M_CREATELINK</td>
<td>Allows creation of a symbolic link.</td>
</tr>
<tr>
<td>REG$M_CREATESUBKEY</td>
<td>Allows creation of subkeys.</td>
</tr>
<tr>
<td>REG$M_ENUMSUBKEYS</td>
<td>Allows enumeration of subkeys.</td>
</tr>
<tr>
<td>REG$M_EXECUTE</td>
<td>Allows read access.</td>
</tr>
<tr>
<td>REG$M_NOTIFY</td>
<td>Allows change notification.</td>
</tr>
<tr>
<td>REG$M_QUERYVALUE</td>
<td>Allows queries of subkey data.</td>
</tr>
<tr>
<td>REG$M_READ</td>
<td>A combination of the following access values:</td>
</tr>
<tr>
<td></td>
<td>REG$K_ENUMSUBKEYS</td>
</tr>
<tr>
<td></td>
<td>REG$K_QUERYVALUE</td>
</tr>
<tr>
<td></td>
<td>REG$K_NOTIFY</td>
</tr>
<tr>
<td>REG$M_SETVALUE</td>
<td>Allows setting of values and data.</td>
</tr>
<tr>
<td>REG$M_WRITE</td>
<td>A combination of the following access values:</td>
</tr>
<tr>
<td></td>
<td>REG$K_CREATESUBKEY</td>
</tr>
<tr>
<td></td>
<td>REG$K_SETVALUE</td>
</tr>
</tbody>
</table>

### REG$SECURITYPOLICY

The REG$SECURITYPOLICY item code is an input item code. It is a longword that specifies the security policy to enforce for the key. It takes the following value:

<table>
<thead>
<tr>
<th>Policy Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_POLICY_NT_40</td>
<td>Access is required to the first key and the requested key (default).</td>
</tr>
</tbody>
</table>

### REG$SEPARATOR

The REG$SEPARATOR item code is an empty item code that provides a separator between sets of item codes.

Using this item code, you can group multiple requests into a single call to the $REGISTRY service. If you use this multiple-request feature, use the REG$SEPARATOR item code to indicate the end of the set of item codes for the current request and that there is another request to process.

### REG$SUBKEYINDEX

The REG$SUBKEYINDEX item code is an input item code. It is a longword that specifies the index of the subkey to retrieve.

### REG$SUBKEYNAME

The REG$SUBKEYNAME item code is an input item code. It is a string of Unicode characters that specifies the name of a subkey. A Unicode character is 4 bytes long.
The 

The item code is an output item code. It is a longword that receives the length (in characters) of a specified key's longest subkey name.

The item code is an output item code. It is a longword that receives the number of subkeys contained in a specified key.

The item code is an input item code. It is a longword that specifies the index of the value to retrieve within a specified key. Note that the value index starts at zero and can be any value up to one less than the count returned by REG$_VALUENUMBER.

The item code is, depending on the function code, either an input or output item code. It is a buffer that contains either the value data component to write to the OpenVMS Registry (input), or it receives a data value component from the OpenVMS Registry (output).

The item code is an output item code. It is a longword that receives the length (in bytes) of the specified key's longest data component value.

The item code is, depending on the function code, either an input or an output item code. It is a string of Unicode characters that specifies the name of a value.

The item code is an output item code. It is a longword that receives the length (in characters) of a specified key's longest value name.

The item code is an output item code. It is a longword that receives the number of values contained in a specified key.

The item code identifies the volatility of an item. As an output, it returns the volatility of the object. On OpenVMS, volatile keys and values are lost when all nodes running an OpenVMS Registry server are rebooted. (In a standalone system, volatile keys and values are lost when the system reboots.)

<table>
<thead>
<tr>
<th>Volatile Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG$K_CLUSTER</td>
<td>The item is removed when the cluster reboots.</td>
</tr>
<tr>
<td>REG$K_NONE</td>
<td>The item is not volatile (default).</td>
</tr>
</tbody>
</table>

**Function Modifiers**

You can optionally specify the high-order bits of a function code value with function modifiers. These individual bits can alter the operation of the function.
For example, you can specify the function modifier $REGM_CASE_SENSITIVE with the function $REGFC_CREATE_KEY. When you use the function and function modifier together, the data passed to the OpenVMS Registry is treated as case sensitive. The two values are written in DEC C as $REGM_CASE_SENSITIVE | $REGFC_CREATE_KEY.

The OpenVMS Registry function modifiers are defined in the header file $REGDEF.H.

$REGM_CASE_SENSITIVE
Use case-sensitive matching for keys and values.

$REGM_DISABLE_WILDCARDS
Treat wildcard characters as normal characters for this function.

$REGM_IGNORE_LINKS
Force the operation to not follow any symbolic links associated with a key or a value.

By default, if a key or value is symbolically linked to another key or value, the system follows all links so that the operation specified by the function code is performed on the linked key or value.

When you specify the $REGM_IGNORE_LINKS function modifier, the operation specified by the function code affects only the specified key or value, not the linked key or value.

By default, if a key or value has a symbolic link, it can not be deleted. If you specify the $REGM_IGNORE_LINKS function modifier, the system deletes the key or value.

$REGM_NOW
Write to disk immediately, regardless of the $REG_CACHEACTION item code value.
Part III
OpenVMS Events

This part contains reference information about OpenVMS Events.
14.1 What are Events?

On a Windows NT system, an event is any significant occurrence in the system or an application—for example, a service starting or stopping, a user logging on or off, or accessing resources. When the system encounters an event, the Event Log service writes the event (or audit entry) in the form of a record that contains date and time, source, category, event number, user, and computer information to a system, security, or application log, creating an audit trail. On Windows NT systems, you display these logs and their recorded events using the Event Viewer.

With COM Version 1.0 for OpenVMS, OpenVMS wrote all COM for OpenVMS events to the DCOM$EVENTLOG.RPT text file. With COM Version 1.1-B for OpenVMS, OpenVMS supports both Windows NT logging and Advanced Server for OpenVMS logging of COM for OpenVMS events. You can now log a COM for OpenVMS event (such as the starting of a COM server on OpenVMS), and review these OpenVMS events from a Windows NT system or an OpenVMS system.

For a detailed review of OpenVMS Events dependencies and a description of how OpenVMS Events interacts with other parts of the OpenVMS infrastructure, see Section 4.8.

14.1.1 Suggested Reading

The following sources can provide you with more information on Events and related topics:

- Third-party books on event logging:

- Other sources:
  - Microsoft Win32 Software Development Kit
    In particular, see the sections about the RegisterEventSource, ReportEvent, and DeregisterEventSource functions, and System Services: Event Logging section.
OpenVMS Events
14.2 Overview of OpenVMS Events

14.2 Overview of OpenVMS Events
The system logs OpenVMS Events to a Windows NT event log, to the Advanced Server for OpenVMS event log, and to a log file on the OpenVMS system.

You can use the following techniques to view OpenVMS Events:
- Windows NT event viewer (see Section 14.2.1)
- Advanced Server for OpenVMS event viewer (see Section 14.2.2)
- OpenVMS event log file (see Section 14.2.3)

14.2.1 Viewing OpenVMS Events Using Windows NT Event Viewer
Use the following procedure to view OpenVMS Events through the Windows NT event viewer:

1. Start the Windows NT event viewer.
   From the Start menu, select Programs, Administrative Tools, Event Viewer.

2. From the Event Viewer window, click the menu bar Log option. Click Select Computer...., and select the OpenVMS system from the list box.

3. From the Event Viewer window, click the menu bar Log option. Click System to display the System event log. The System event log contains the COM for OpenVMS events.
   To display COM for OpenVMS events only, use the following procedure:
   - From the Event Viewer window, click the menu bar View option. Click Filter Events....
     The system displays the Filter window.
   - On the Filter window, click the Source: list box. From the list, choose DCOM.

14.2.2 Viewing OpenVMS Events Using Advanced Server for OpenVMS Event Viewer
Use the following procedure to view the COM for OpenVMS events:

1. Ensure that the Advanced Server for OpenVMS is running.

2. Enter the following Advanced Server for OpenVMS ADMINISTRATOR command:

   \$ ADMIN SHOW EVENTS/TYPE=SYSTEM/SOURCE=DCOM/FULL

   The viewer displays COM for OpenVMS events only, along with any additional information associated with the COM for OpenVMS event.

14.2.3 Event Logging on OpenVMS Only
In some cases, you might want to write and view COM for OpenVMS events only on an OpenVMS system. In place of the Windows NT log, Compaq has included an alternate event logger that writes COM event information to an OpenVMS file. You can find this file in the following location:

   SYS$MANAGER:DCOM$EVENTLOG.RPT
COM for OpenVMS creates this event logging report automatically when the COM server (DCOM$RPCSS) encounters an error. The event logger appends new events at the bottom (end) of the file. A logged event has the following format:

```
  event type : ddd mmm dd hh:mm:ss yyyy
  First event message
```

```
  event type : ddd mmm dd hh:mm:ss yyyy
  Second event message
```

Example 14–1 shows the contents of an event log.

**Example 14–1 Sample OpenVMS Event Log**

```
$ Type SYS$MANAGER:DCOM$EVENTLOG.RPT

1  ERROR : Tue Sep 15 11:18:54 1998
    Unable to start a DCOM Server: {5E9DDEC7-5767-11CF-BEAB-00AA006C3606}
    Runas (null)/SMITH

    Happened while starting: device:[account]SSERVER.EXE

2  ERROR : Tue Sep 15 19:14:45 1998
    The server {0C092C21-882C-11CF-A6BB-0080C7B2D682} did not register
    with DCOM within the required timeout.
```

1 The system logged the first error event on Tue Sep 15 11:18:54 1998. The COM server (DCOM$RPCSS) was unable to start the COM application `device:[account]SSERVER.EXE` on behalf of the client running under the SMITH account. (The client may have received an error such as "access denied.") The resulting Windows NT error was 1326, which translates as "Logon failure: unknown user name or bad password."

If you see this error, check the validity of the user account using the OpenVMS Authorize utility (AUTHORIZE).

2 The system logged the second error event on Tue Sep 15 19:14:45 1998. The COM server (DCOM$RPCSS) was able to start the COM application `{0C092C21-882C-11CF-A6BB-0080C7B2D682}`, but the application did not run successfully. The application failed to register with DCOM$RPCSS within the specified time limit. (The client may have received an error such as "Server execution failed" `CO_E_SERVER_EXEC_FAILURE`.)

If you see this error, run the server application interactively to determine its integrity.
OpenVMS Events Routine
NTA$EVENTW

NTA$EVENTW
Interface to OpenVMS Events

Allows an application to record information in the event log files.
The NTA$EVENTW routine completes all operations synchronously.

Format

NTA$EVENTW [nullarg], func, itmlst, evsb

Arguments

nullarg
OpenVMS usage: reserved
type: longword (unsigned)
access: read only
mechanism: by value

Reserved for Compaq use.

func
OpenVMS usage: function code
type: longword (unsigned)
access: read only
mechanism: by value

Function code specifying the function NTA$EVENTW is to perform. The func argument is a longword containing this function code. The $EVENTDEF macro defines the names of each function code.

itmlst
OpenVMS usage: address of item list
type: 64-bit address
access: read only
mechanism: by value

Item list specifying information about the event source or the event. The itmlst argument is the 64-bit address of a list of item descriptors, each of which describes an item of information. An item list in 64-bit format is terminated by a quadword of 0.

The following diagram shows the 64-bit format of a single item descriptor.
OpenVMS Events Routine
NTA$EVENTW

evsb
OpenVMS usage: address of status block
type: 64-bit address
access: write only
mechanism: by reference

Event status block to contain the completion status for the requested operation.

NTA$EVENTW sets the status block to 0 upon request initiation. Upon request completion, the EVT$L_VMS_STATUS field contains the primary (OpenVMS) completion status for the operation.

If an error occurs, EVT$L_NT_STATUS (if non-zero) is the secondary error status to further define the error condition.

Function Codes

EVT$_FC_REGISTER_EVENT_SOURCE
Open an association with an event log.

<table>
<thead>
<tr>
<th>Item code</th>
<th>Required</th>
<th>Parameter</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVT$_SERVER_NAME</td>
<td>No</td>
<td>Input</td>
<td>String (4-byte Unicode)</td>
</tr>
<tr>
<td>EVT$_SOURCE</td>
<td>No</td>
<td>Input</td>
<td>String (4-byte Unicode)</td>
</tr>
<tr>
<td>EVT$_HANDLE</td>
<td>Yes</td>
<td>Output</td>
<td>Unsigned longword</td>
</tr>
</tbody>
</table>

•  EVT$_SERVER_NAME
  The universal naming convention (UNC) name of the server on which this operation is to be performed.
  UNC names have the form \\server\share\path\file. This item must be zero or unspecified. This performs the operation on an available Advanced Server for OpenVMS server in the cluster.

•  EVT$_SOURCE
  The name of the application that logs the event. This field associates an application message file that contains descriptive text with the application’s event log entries.
OpenVMS Events Routine
NTA$EVENTW

If specified, the source must be a subkey of the Eventlog\System key, the Eventlog\Security key, or the Eventlog\Application registry key. For example, a source name of Myapp indicates a registry entry in the following:

HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Eventlog\Application\Myapp

The Myapp registry value EventMessageFile names the path and message file to be used to translate this application's events.

The source can be unspecified or specified as NULL. In this case, the system logs events to the Application log file but the application logs no message file (and, as a result, no replacement text) for the associated events.

• EVT$$_HANDLE
Returns a handle to the Application event log. This handle is required input for other $EVENT functions.
On failure, a handle of 0 is returned. This handle is outside the responsibility of the CloseHandle API.

EVT$$_FC_REPORT_EVENT
Generate an event log entry.

<table>
<thead>
<tr>
<th>Item code</th>
<th>Required</th>
<th>Parameter</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVT$_HANDLE</td>
<td>Yes</td>
<td>Input</td>
<td>Unsigned longword</td>
</tr>
<tr>
<td>EVT$_EVENT_TYPE</td>
<td>Yes</td>
<td>Input</td>
<td>Word mask</td>
</tr>
<tr>
<td>EVT$_EVENT_CATEGORY</td>
<td>No</td>
<td>Input</td>
<td>Word</td>
</tr>
<tr>
<td>EVT$_EVENT_ID</td>
<td>Yes</td>
<td>Input</td>
<td>Longword</td>
</tr>
<tr>
<td>EVT$_USER_SID</td>
<td>No</td>
<td>Input</td>
<td>NT Security ID</td>
</tr>
<tr>
<td>EVT$_NUMSTRINGS</td>
<td>No</td>
<td>Input</td>
<td>Word</td>
</tr>
<tr>
<td>EVT$_DATASIZE</td>
<td>No</td>
<td>Input</td>
<td>Longword</td>
</tr>
<tr>
<td>EVT$_STRING_ARRAY</td>
<td>No</td>
<td>Input</td>
<td>Array of varying-length descriptors. (4-byte Unicode)</td>
</tr>
<tr>
<td>EVT$_RAW_DATA</td>
<td>No</td>
<td>Input</td>
<td>Binary data</td>
</tr>
</tbody>
</table>

• EVT$_HANDLE
Value returned by a previous EVT$$_FC_REGISTER_EVENT_SOURCE call.

• EVT$_EVENT_TYPE
Indicates the severity of the event. The type is one of the following:

EVT$$_SUCCESS
EVT$$_ERROR
EVT$$_WARNING
EVT$$_INFO
EVT$$_AUDIT_SUCCESS
EVT$$_AUDIT_FAILURE

The severity type maps to its Windows NT equivalent, defined in WINNT.H.

• EVT$_EVENT_CATEGORY
An integer value from 1 to 65535. EVT$_EVENTCATEGORY is unique to a particular source.
EVT$EVENTCATEGORY allows an application to divide its message file into sections, each indexed by event ID. If you do not specify a category, the system defaults to a category of zero.

- EVT$EVENT_ID
  An unlimited integer value. This value indexes the category in an application message file that locates the text string displayed for this event message. The event ID is unique to a particular source.

- EVT$USER_SID
  The optional Windows NT Security ID of the thread logging the event. An application that has acquired Windows NT credentials through the $PERSONA system service can obtain its SID through calls to the OpenProcessToken and GetTokenInformation Win32 APIs. The format is opaque to this service.

- EVT$NUMSTRINGS
  A count of the strings specified in the EVT$STRINGARRAY item code.

- EVT$DATASIZE
  Length in bytes of the buffer indicated by the EVT$RAWDATA item code.

- EVT$STRINGARRAY
  An array of string pointers. Each entry points to a null terminated string. A description string in a message file can contain string placeholders in the form %n, where %1 indicates the first placeholder. Strings specified in this array replace these placeholders when the system displays the event message.

- EVT$RAWDATA
  Allows you to include binary data in an event message. For example, you might use this to dump a data structure from a failing component.

EVT$DEREGISTEREVENTSOURCE
Close an association with an event log.

<table>
<thead>
<tr>
<th>Item code</th>
<th>Required</th>
<th>Parameter</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVT$HANDLE</td>
<td>Yes</td>
<td>Input</td>
<td>Unsigned longword</td>
</tr>
</tbody>
</table>

- EVT$HANDLE
  Value returned by a previous EVT$FCREGISTEREVENTSOURCE call.

### Description

The NTA$EVENTW routine allows you to register and deregister an event source and report event data. This event logging allows you to record information from within an application. You can use the events routines to track progress within an application or identify problems encountered by an application.

The NTA$EVENTW routine completes synchronously; that is, control is returned to the caller only after the request completes.

Use the following process to write event data:

1. **Register the event source.**
   - This operation defines the event log to which the system writes event data.

2. **Report the event.**
   - This operation causes the system to write the information to the appropriate event log.

3. **Deregister the event source.**
   - This operation frees resources acquired as part of the event source registration operation.

### Condition Values Returned

- **SS$_NORMAL**—Service completed successfully.
- **SS$_ACCVIO**—One of the arguments cannot be read/written.
- **SS$_BADPARAM**—Bad parameter.
- **SS$_NOPRIV**—Insufficient privilege to access the specified event log.
- **SS$_TIMEOUT**—Request timed out.
- **SS$_UNREACHABLE**—Events service unavailable.
- **SS$_REJECT**—The Windows NT LAN Manager server encountered an error. See the Win32 status for more information.
14.3 Writing Your Own Events

By default, the system logs DCOM events generated by COM for OpenVMS. In addition to recording COM for OpenVMS events, the system can also log COM application events for COM applications that you create.

The COM for OpenVMS kit includes sample code that shows how to generate an application event using Win32 APIs. You can use this example as is on a Windows NT system. The example also builds correctly using the instructions for building COM for OpenVMS applications on OpenVMS (to get the required header files from DCOM$LIBRARY). See Chapter 7 for these instructions. The example also includes the linking instructions to build the example using Wind/U.

14.4 Troubleshooting OpenVMS Events

Errors that occur during event reporting can be difficult to trace because of the number of intervening software layers through which the event passes. The following list describes how OpenVMS Events pass through other software layers until they are recorded in the Windows NT log.

1. An application calls one of the Win32 event functions (RegisterEventSource, ReportEvent, or DeregisterEventSource).
2. Using the supplied arguments, the Win32 API builds an appropriate item list and calls the NTAEVENTW routine.
3. The NTAEVENTW routine validates the information supplied (function code, item list, and so on) and builds an appropriate item list for the SYS$ACM system service.
   If NTAEVENT detects any errors NTAEVENT returns the errors to the Win32 API using R0 and the event status block.
4. The SYS$ACM system service validates the information and passes it to the NT ACME.
   If SYS$ACM detects any errors, SYS$ACM returns the errors to NTAEVENTW using R0 and the ACM status block.
5. The NT ACME passes the supplied information (using an IPC pipe) to a dispatcher in the Advanced Server for OpenVMS.
   If the NT ACME detects any errors, the NT ACME returns the errors to the caller using the ACM status block.
6. The Advanced Server for OpenVMS dispatcher validates the information and calls the appropriate routines to perform the requested operation (register, report, or deregister).
   If the Advanced Server for OpenVMS detects any errors, it reports the errors to the NT ACME. The NT ACME passes the errors back to the other callers.

Checking the contents of the event status block help you determine where the failure might have happened. Table 14–1 lists (in order of importance) the checks you should perform.
## 14.4 Troubleshooting OpenVMS Events

### Table 14–1 Troubleshooting OpenVMS Events Failures

<table>
<thead>
<tr>
<th>R0 Status</th>
<th>Status Field Value</th>
<th>Component to Check</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failure (bit 0 clear)</td>
<td>EVT$L_NT_STATUS field is nonzero.</td>
<td>Error most likely occurred within Advanced Server for OpenVMS.</td>
</tr>
<tr>
<td>Failure</td>
<td>EVT$L_VMS_STATUS field is nonzero and the EVT$L_NT_STATUS is zero.</td>
<td>Error most likely occurred within the SYS$ACM system service or the NT ACME.</td>
</tr>
<tr>
<td>Failure</td>
<td>EVT$L_VMS_STATUS is zero and EVT$L_NT_STATUS is zero.</td>
<td>Error most likely occurred within the SYS$ACM system service.</td>
</tr>
</tbody>
</table>

---

**Note**

The Win32 API usually converts the error status to an appropriate NT error status code and makes it available through the GetLastError Win32 API. (The status returned by the event API simply indicates a generic failure.)
This part contains reference information about COM for OpenVMS and the OpenVMS Registry.

The appendixes provide information about the MIDL compiler, troubleshooting tips, COM sample code, running COM for OpenVMS in an unauthenticated environment, and APIs and interfaces.

This part also includes coupons for related COM books, a glossary, and a list of acronyms.
### A.1 Mode

<table>

<tr>
<td>/o filename</td>
<td>Redirects output from screen to a file</td>
</tr>
<tr>
<td>/W{0</td>
<td>1</td>
</tr>
<tr>
<td>/WX</td>
<td>Report warnings at specified /W level as errors</td>
</tr>
</tbody>
</table>
B.1 RPC Troubleshooting

When you perform a significant number of simultaneous NTLM authentications, the following errors are likely to occur. Several factors affect the number of simultaneous NTLM authentications, however, you are most likely to see these errors when the network is congested or when the RPC application server does not respond to requests in a timely manner. The errors are returned as standard RPC application return values.

Table B–1 provides a description of the suspected cause and possible workarounds.

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause/Corrective Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPC_S_CONNECTION_REJECTED</td>
<td>This error is seen by the client application as an exception when using either DECnet Phase IV or DECnet Phase V as a transport and when the server is heavily loaded servicing other DECnet clients. The system returns this error when the client RPC run time binds to a newly created socket and the socket call returns error 61 (connection refused). Possible solutions:</td>
</tr>
<tr>
<td></td>
<td>1. Raise DECnet resource quotas.</td>
</tr>
<tr>
<td></td>
<td>2. Enhance the client RPC program to catch the exception and either retry the RPC or choose a different server.</td>
</tr>
</tbody>
</table>

(continued on next page)
Troubleshooting
B.1 RPC Troubleshooting

Table B–1 (Cont.) RPC Errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause/Corrective Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPC_S_CONNECTION_TIMED_OUT</td>
<td>This error is seen by the client application as an exception when using TCP or DECnet as a transport and when the server is heavily loaded. The system returns this error when the client RPC run time binds to a newly created socket and the server takes too long to either accept or reject the connection. Possible solutions: 1. Configure TCP or DECnet to wait longer before sockets time out. 2. Enhance the RPC client application to call <code>rpc_mgm_t_set_com_timeout()</code> and instruct the RPC run time to retry when it gets this socket error. 3. Recode the client RPC program to catch the exception and either retry the RPC or choose a different server.</td>
</tr>
<tr>
<td>RPC_S_ASSOC_SHUTDOWN</td>
<td>This error is seen by the client application as an exception when using TCP or DECnet as a transport and when the client is heavily loaded (usually when the client is also an RPC server). After an RPC server receives an RPC_BIND packet from a client and the server sends back an RPC_BIND_ACK packet to the client, the server expects to receive a REQUEST packet within 12 seconds. If the client does not send the REQUEST packet within 12 seconds, the RPC server deletes the association and sends a SHUTDOWN packet to the client. The client RPC run time raises an exception to the RPC application. This scenario is likely to occur when the client RPC application is also acting as an RPC server and that RPC server is already heavily loaded. Possible solutions: 1. Implement the client RPC program to catch the exception and either retry the RPC or choose a different server.</td>
</tr>
</tbody>
</table>
Table B–1 (Cont.)  RPC Errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause/Corrective Actions</th>
</tr>
</thead>
</table>
| RPC_S_COMM_FAILURE | This error is seen by the client application as an exception when using DG (UDP) as a transport and when the RPC server is heavily loaded.  
The RPC client sends a REQUEST packet to the server. If the client does not get a WORKING packet response from the server within 30 seconds, the client sends a PING packet to the server to see if the server is still active and working on the client's request. If the RPC server is under heavy load, the server may not return the WORKING packet to the client before the client times out.  
**Possible solutions:**  
1. RPC client application can call rpc_mgmt_set_com_timeout() to instruct the RPC run time to wait longer than 30 seconds before timing out.  
2. Implement the client RPC program to catch the exception and either retry the RPC or choose a different server. |

B.2 Troubleshooting the ACME server

Use the following procedure to troubleshoot problems with the ACME server:

1. Verify that the ACME_SERVER process is running (use the SHOW SERVER ACME command) and verify there is a connection between the MSV1_0 ACME agent and the Advanced Server for OpenVMS process.

2. If no connection exists, verify that the PWRK$ACME_SERVER logical name contains the SCS node names of systems in the cluster that are running the Advanced Server for OpenVMS process.

3. If the PWRK$ACME_SERVER logical name is defined correctly, verify that the Advanced Server for OpenVMS process is running on the systems specified (look for the PWRK$LMSRV process).

4. If authentications are failing, check the following:
   - Interdomain authentication (EASTUSHOKSK\JOE) requires trust relationships. Use the Advanced Server for OpenVMS ADMINISTER ADD TRUST[/TRUSTED] or [/PERMITTED] command to establish the desired trust relationships between two domains.
   - Windows NT passwords are case sensitive. Be sure you have entered the passwords using the correct case.
   - Windows NT user either has no OpenVMS hostmap account or maps to an invalid OpenVMS account (the default UAF mapping is PWRK$DEFAULT, which has DISUSER flag set). Use the Advanced Server for OpenVMS ADMINISTER ADD HOSTMAP command to map the Windows NT user name to a valid OpenVMS account.
Troubleshooting

B.2 Troubleshooting the ACME server

- Windows NT user account is invalid, expired, disabled, or has an invalid password. Use the Advanced Server for OpenVMS ADMINISTER SHOW USER/FULL command to display the complete user account information. Use the Advanced Server for OpenVMS ADMINISTER SHOW ACCOUNT POLICY command to display the domain policy information.

- OpenVMS account does not have EXTAUTH flag set. In AUTHORIZE, use the UAF utility MODIFY user-name/FLAG=EXTAUTH command. (You can override this requirement by setting the IGNORE_EXTAUTH bit (bit number 11 [decimal]) in the SECURITY_POLICY system parameter.)

- UAF record flag is set to DISUSER. In AUTHORIZE, use the UAF utility MODIFY user-name/FLAG=NODISUSER command.

- UAF record modal restrictions prevent “login” (check local dialup, remote, network, and batch access restrictions). In AUTHORIZE, use the UAF utility MOD user-name/LOCAL (or DIALUP, BATCH, NETWORK,REMOTE) keywords; INTERACTIVE sets LOCAL, DIALUP, and REMOTE access restrictions.

- Intrusion subsystem has entered break-in evasion mode because the number of failed logins has exceeded the system threshold (set by SYSGEN parameter LGI_BRK_LIM). Use the SHOW INTRUSION command to view the intrusion database. Use the DELETE/INTRUSION source command to remove entries from the database. If the LGI_BRK_DISUSER is set, the UAF record may be set to DISUSER. Use the OpenVMS AUTHORIZE command to reset the flag.

B.3 Troubleshooting the DCOM$RPCSS Process

The DCOM$RPCSS process must be running to run any COM for OpenVMS applications on your OpenVMS system. The DCOM$STARTUP.COM command file is automatically starts this process. If you have problems running COM for OpenVMS applications, check that this process is running. Use the following command:

```
$ SHOW SYSTEM
```

If the process is initializing, the process name is DCOM$STARTUP-**. If the process is in its normal running state, the process name is be DCOM$RPCSS.

Check the SYS$MANAGER:DCOM$RPCSS.OUT log file for error messages from the DCOM$RPCSS process. The messages can include the following:

- %ACME-E-PWDEXPIRED, password has expired
  
  If the DCOM$RPCSS log file contains this error, do the following:

  1. Run the Advanced Server for OpenVMS ADMIN utility and to change the password of the DCOM$RPCSS account. See Section 6.2.1.

  2. Update the COM for OpenVMS Service Control Manager password file. See Section 6.2.1.
B.4 Troubleshooting the Advanced Server for OpenVMS

The Advanced Server for OpenVMS must be running to authenticate users with NT credentials.

A troubleshooter may wish to enable the audit policy to capture failures for logonoff and system events. For example, on systems running Advanced Server for OpenVMS, issue the command:

```
$ ADMINISTER SET AUDIT POLICY/AUDIT/FAILURE=(LOGONOFF,SYSTEM)
```

To monitor events, issue the commands:

```
$ ADMINISTER SHOW EVENT /FULL /TYPE=SYSTEM
$ ADMINISTER SHOW EVENT /FULL /TYPE=SECURITY
```

For more information, the Advanced Server for OpenVMS Server Administrator’s Guide provides a chapter on Monitoring Events and Troubleshooting.

Additionally, the system manager may want to check the system operator log, SYSMANAGER:OPERATOR.LOG, to verify that no network errors have occurred.

B.5 Troubleshooting COM for OpenVMS Application Failures

This section describes problems you may encounter when running a COM application.

B.5.1 Access Denied Failures

For information on access denied failures, see Section 5.4.6.
C

Cookbook Examples: Building a Sample Application on OpenVMS

C.1 COM Example (Sample1)

This sample implements a COM client and server in which the component provides two interfaces: IX and IY. The client also queries the component for a third interface, IZ, an interface that the component does not provide.

This sample demonstrates connectivity between two OpenVMS systems, between two Windows NT systems, or between an OpenVMS system and a Windows NT system.

C.1.1 OpenVMS Instructions

The following sections describe how to build the application on an OpenVMS system.

C.1.1.1 Building the Application on OpenVMS

Copy files from the DCOM examples directory to your local directory. For example:

```bash
$ set default mydisk:[mydirectory]
$ copy dcom$examples:[sample1]*.* []
```

To build the application, run the following command procedure:

```bash
$ @build_sample1
```

If you have MMS, you can use the included description file as follows:

```bash
$ MMS/DESCRIPTION=BUILD_SAMPLE1.MMS
```

The BUILD file builds and registers both the in-process and out-of-process servers.
C.1 COM Example (Sample1)

C.1.1.2 Registering the Application on OpenVMS

The build procedure automatically registers both DISPCMPNT$SHR.EXE and DISPCMPNT.EXE. To register the components manually, use the following procedure:

- To register the in-process server, use the REGSVR32 utility as follows:
  
  $ regsvr32 :== $DCOM$REGSVR32.EXE
  $ regsvr32 path-nameDISPCMPNT$SHR.EXE

- To unregister the in-process server, use the REGSVR32 utility as follows:
  
  $ regsvr32 /u path-nameDISPCMPNT$SHR.EXE

- To register the out-of-process server:
  
  $ dispcmpnt :== $path-nameDISPCMPNT.EXE
  $ dispcmpnt /regserver

- To unregister the out-of-process server:
  
  $ dispcmpnt /unregserver

- To register the Proxy Stub, use the REGSVR32 utility as follows:
  
  $ regsvr32 path-namePROXY$SHR.EXE

- To unregister the Proxy Stub, use the REGSVR32 utility as follows:
  
  $ regsvr32 /u path-namePROXY$SHR.EXE

C.1.1.3 Running the Application on OpenVMS as an Out-of-Process Server

To run the sample where the component is an out-of-process server, run DISPCMPNT.EXE. When the system displays the Server: Waiting message from the component, run the client in a separate window or terminal session.

- Window (or terminal session) 1:
  
  $ run dispcmpnt

- Window (or terminal session) 2:
  
  $ client :== $path-nameCLIENT.EXE
  For OutProc:
  $ client
  2

The client displays the following:

To which server do you want to connect?
1) In-Process Server
2) Out-of-Process Server

Enter 2 to select the out-of-process server.

C.1.1.4 Running the Application on OpenVMS and Specifying a Remote Server

Run DISPCMPNT.EXE on the system you designate as the remote machine (or server system). The remote system can also be a Windows NT system. When you receive the Server: Waiting message from the component, run the client on the system you designate as the local machine (or client system). For example:

$ client :== $path-nameCLIENT.EXE
$ client remote-system-name
  2
  $
The client displays the following:

To which server do you want to connect?
1) In-Process Server
2) Out-of-Process Server
:

Enter 2 to select remote server execution, out-of-process server.

C.1.1.5 Running the Application on OpenVMS as an In-Process Server
To run the sample where the component is an in-process server, run only the client. For example:

For InProc:
$ client 1 $  

The client displays the following:

To which server do you want to connect?
1) In-Process Server
2) Out-of-Process Server
:

Enter 1 to select the in-process server.

C.1.2 Windows NT Instructions
The following sections describe how to build the application on a Windows NT system.

Note
In order to build Visual C++ applications from a DOS window, you must first set up a number of environment variables. If you did not select the option to have these variables set up automatically when you installed Visual C++, you will need to set them up each time you create a DOS window. To set up these variables, execute the file

C:\Program Files\Microsoft Visual Studio\VC98\BIN\VCVARS32.BAT

C.1.2.1 Building the Application on Windows NT
Copy the README-SAMPLE1.TXT file and the following files from the COM examples directory to your Windows NT system:

CLIENT.CXX
DCLIENT.CXX
DISPCMPNT.CXX
DISPCMPNT.DEF
DISPCMPNT.IDL
MAKE-ONE.
MAKEFILE.BAT
REGISTRY.CXX
REGISTRY.H

Build the sample using the MAKEFILE.BAT file. For example:

> MAKEFILE

The Makefile builds and registers both the in-process and out-of-process servers.
C.1 COM Example (Sample1)

C.1.2.2 Registering the Application on Windows NT

The build procedure `make-one` automatically registers `DISPCMPNT.DLL`, `PROXY.DLL`, and `CMPNT.EXE` as follows:

```
regsvr32 -s Dispcmpnt.dll
regsvr32 -s Proxy.dll
```

To unregister the application, enter the following:

```
regsvr32 -u Dispcmpnt.dll
regsvr32 -u Proxy.dll
```

C.1.2.3 Running the Application on Windows NT

Run `CLIENT`. Follow the same procedure as described for OpenVMS for running the application as an in-process server (Section C.1.1.5) and out-of-process server (Section C.2.1.3).

Use the name of a remote machine (UNC or DNS) as an argument to instantiate the object on the remote machine. For example:

```
>Client hostname ! point the client at the remote system
2 ! means outproc invocation
```

C.2 Automation Example (Dispatch_Sample1)

This sample implements the Automation component server as a dual interface. There are two separate clients: `Dclient`, which connects to the dual interface through the dispinterface, and `Client`, which is a COM client implementation that connects through the `IUnknown` interface (using a v-table).

This sample demonstrates connectivity between two OpenVMS systems, between two Windows NT systems, or between an OpenVMS system and a Windows NT system.

C.2.1 OpenVMS Instructions

The following sections describe how to build the application on an OpenVMS system.

C.2.1.1 Building the Application on OpenVMS

Copy files from the `DCOM` examples directory to your local directory. For example:

```
$ set default mydisk:[mydirectory]
$ copy dcom$examples:[dispatch_sample1]*.* []
```

To build the application, run the following command procedure:

```
$ @build_dispatch_sample1
```

If you have MMS, you can use the included description file as follows:

```
$ MMS/DESCRIPTION=BUILD_DISPATCH_SAMPLE1.MMS
```

The `BUILD` file builds and registers both the in-process and out-of-process servers.
C.2 Automation Example (Dispatch_Sample1)

C.2.1.2 Registering the Application on OpenVMS

The build procedure automatically registers both DISPCMPNT$SHR.EXE and DISPCMPNT.EXE. To register the components manually, use the following procedure:

- To register the in-process server, use the REGSVR32 utility as follows:
  
  ```sh
  $ regsvr32 :== $DCOM$REGSVR32.EXE
  $ regsvr32 path-name DISPCMPNT$SHR.EXE
  ```

- To unregister the in-process server, use the REGSVR32 utility as follows:

  ```sh
  $ regsvr32 /u path-name DISPCMPNT$SHR.EXE
  ```

- To register the out-of-process server:

  ```sh
  $ dispcmpnt :== $path-name DISPCMPNT.EXE
  $ dispcmpnt /regserver
  ```

- To unregister the out-of-process server:

  ```sh
  $ dispcmpnt /unregserver
  ```

C.2.1.3 Running the Application on OpenVMS as an Out-of-process Server

To run the sample where the component is an out-of-process server, run DISPCMPNT.EXE. When the system displays the Server: Waiting message from the component, run the client in a separate window or terminal session.

- Window (or terminal session) 1:
  
  ```sh
  $ run dispcmpnt
  ```

- Window (or terminal session) 2:
  - For dispatch client:
    
    ```sh
    $ run dclient
    ```
  - For COM client:
    
    ```sh
    $ run client
    ```

The client displays the following:

To which server do you want to connect?

1) In-Process Server
2) Out-of-Process Server

Enter 2 to select the out-of-process server.

C.2.1.4 Running the Application on OpenVMS and Specifying a Remote Server

Run DISPCMPNT.EXE on the system you designate as the remote machine (or server system). The remote system can also be a Windows NT system. When you receive the Server: Waiting message from the component, run the client on the system you designate as the local machine (or client system). For example:

To use the COM client, enter the following:

```sh
$ client :== $path-name CLIENT.EXE
$ client remote-system-name
```

To which server do you want to connect?

1) In-Process Server
2) Out-of-Process Server

;
C.2 Automation Example (Dispatch_Sample1)

Enter 2 to select remote server execution, out-of-process server.

C.2.1.5 Running the Application on OpenVMS as an In-Process Server

To run the sample where the component is an in-process server, run only the client. For example:

- For dispatch client:
  $ run dclient
- For COM client:
  $ run client

The client displays the following:

To which server do you want to connect?
1) In-Process Server
2) Out-of-Process Server
:

Enter 1 to select the in-process server.

C.2.2 Windows NT Instructions

The following sections describe how to build the application on a Windows NT system.

---

**Note**

In order to build Visual C++ applications from a DOS window, you must first set up a number of environment variables. If you did not select the option to have these variables set up automatically when you installed Visual C++, you will need to set them up each time you create a DOS window. To set up these variables, execute the file

C:\Program Files\Microsoft Visual Studio\VC98\BIN\VCVARS32.BAT

---

C.2.2.1 Building the Application on Windows NT

Copy the README-DISPATCH-SAMPLE1.TXT file and the following files from the COM examples directory to your Windows NT system:

- CLIENT.CXX
- DCLIENT.CXX
- DISPCOMPNT.CXX
- DISPCOMPNT.DEF
- DISPCOMPNT.IDL
- MAKE-ONE.
- MAKEFILE.BAT
- REGISTRY.CXX
- REGISTRY.H

Build the sample using the MAKEFILE.BAT file. For example:

C:> MAKEFILE

The Makefile builds and registers both the in-process and out-of-process servers.
C.2.2.2 Registering the Application on Windows NT

The build procedure `make-one` automatically registers `DISPCMPNT.DLL`, `PROXY.DLL`, and `DISPCMPNT.EXE` as follows:

```
regsvr32 -s Dispcmpnt.dll
Dispcmpnt /RegServer
```

To unregister the application, enter the following:

```
regsvr32 -u Dispcmpnt.dll
Dispcmpnt /UnRegServer
```

C.2.2.3 Running the Application on Windows NT

Run `DCLIENT` or `CLIENT`. Follow the same procedure as described for OpenVMS for running the application as an in-process server (Section C.2.1.5) and an out-of-process server (Section C.2.1.3).

Use the name of a remote machine (UNC or DNS) as an argument to instantiate the object on the remote machine.

C.3 Cross-Domain Security Example (CLIENTAUTH)

This sample shows how you can authenticate a remote client that is not in the server’s domain or in a domain that has a trust with the server’s domain. The client must pass to this application the credentials (user name, domain and password) of an account on the server’s domain that is allowed access and launch permissions. In fact, the client need not be in any domain and can be anywhere on the network. This is demonstrated in Section C.3.1.3.

C.3.1 OpenVMS Instructions

The following sections describe how to build the application on an OpenVMS system.

```
Note
Not all functionality is present in the underlying Windows NT infrastructure on OpenVMS. Therefore, you cannot currently run the client on OpenVMS. This sample works when you run the client on Windows NT and the server on OpenVMS.
```

Copy files from the DCOM examples directory to your local directory.

```
$ set default mydisk:[mydirectory]
$ copy dcom$examples:[clientauth]*.* []
```

To build the application, run the command procedure:

```
$ @build_clientauth
```

The BUILD file builds and registers both the in-process and out-of-process servers.
C.3 Cross-Domain Security Example (CLIENTAUTH)

C.3.1.1 Registering the Application on OpenVMS

PROXY$SHR.EXE, CLIENTAUTH$SHR.EXE, and CLIENTAUTH.EXE are registered automatically by the build procedure. To register the application manually, use the following procedure:

- To register the in-process server, use the REGSVR32 utility provided:
  
  ```
  $ regsvr32 == $DCOM$REGSVR32.EXE
  $ regsvr32 <path-name>CLIENTAUTH$SHR.EXE
  $ regsvr32 <path-name>PROXY$SHR.EXE
  ```

- To unregister the in-process server:
  
  ```
  $ regsvr32 /u <path-name>CLIENTAUTH$SHR.EXE
  $ regsvr32 /u <path-name>PROXY$SHR.EXE
  ```

- To register the out-of-process server:
  
  ```
  $ clientauth == $<path-name>CLIENTAUTH.EXE
  $ clientauth /regserver
  ```

- To unregister the out-of-process server:
  
  ```
  $ clientauth /unregserver
  ```

C.3.1.2 Running the Application on OpenVMS as an Out-of-Process Server

To run the sample where the component is an out-of-process server, run CLIENTAUTH.EXE. When you receive the server waiting message from the component, run the client (in a separate window or terminal session).

- Window (or terminal session) 1:
  
  ```
  $ run clientauth
  ```

- Window (or terminal session) 2:
  
  ```
  $ client == $<path-name>CLIENT.EXE
  For OutProc:
  $ client
  2
  $ 2
  ```

The client will ask whether you want to start an in-process server or an out-of-process server. Select out-of-process server.

C.3.1.3 Running the Application on OpenVMS and Specifying a Remote Server

Run CLIENTAUTH.EXE on the system you designate as the remote machine, or server system. The remote system can also be a Windows NT system. When you receive the server waiting message from the component, run the client on the system you designate as the local machine, or client system.

```
$ client == $<path-name>CLIENT.EXE
$ client <remote-system-name>
2
$ Please enter account to use on remote machine:
$ Username:
$ Domain:
$ Password:
```

The client will ask whether you want to start an in-process server or an out-of-process server. For remote server execution, select out-of-process server. You will then be prompted to enter the user name, domain and password of an account on the remote server. Make sure this account has been granted access and launch permissions to the component (see Section 6.3.2).
C.3.1.4 Running the Application on OpenVMS as an In-Process Server

To run the sample where the component is an in-process server, run only the client:

For InProc:
$ client
1
$

The client will ask whether you want to start an in-process server or an out-of-process server. Select in-process server.

C.3.2 Windows NT Instructions

The following sections describe how to build the application on a Windows NT system.

Note

In order to build Visual C++ applications from a DOS window, you must first set up a number of environment variables. If you did not select the option to have these variables set up automatically when you installed Visual C++, you will need to set them up each time you create a DOS window. To set up these variables, execute the file

C:\Program Files\Microsoft Visual Studio\VC98\BIN\VCVARS32.BAT

C.3.2.1 Building the Application on Windows NT

Copy this file README-CLIENTAUTH.TXT and the following files from the DCOM examples directory to your Windows NT system:

CLIENT.CXX
CLIENTAUTH.CXX
CLIENTAUTH.DEF
CLIENTAUTH.IDL
GUIDS.CXX
MAKE-ONE.
MAKEFILE.BAT
PROXY.DEF
REGISTRY.CXX
REGISTRY.H

Build the sample using the MAKEFILE.BAT file.

> MAKEFILE

The Makefile builds and registers both the in-process and out-of-process servers.

C.3.2.2 Registering the Application on Windows NT

CLIENTAUTH.DLL, PROXY.DLL, and CLIENTAUTH.EXE are registered automatically by the build procedure <make-one>:

regsvr32 -s clientauth.dll
regsvr32 -s Proxy.dll
clientauth /RegServer

To unregister:

regsvr32 -u clientauth.dll
regsvr32 -u Proxy.dll
clientauth /UnRegServer
C.3.2.3 Running the Application on Windows NT

Run CLIENT. Follow the same procedure as described for OpenVMS for running application as in-process and out-of-process (see Section C.3.1.2 and Section C.3.1.4).

Do not use command line arguments to instantiate the object on the current machine. Use the name of a remote machine (UNC or DNS) as an argument to instantiate the object on the remote machine.

(i.e) >Client hostname
     >
     >Username:
     >Domain:
     >Password:

! point the client at the remote system
! means outproc invocation
Upgrading to COM Version 1.1-B for OpenVMS from COM Version 1.0 for OpenVMS

D.1 Upgrading from Earlier Versions of COM for OpenVMS

The following sections describe tasks you must complete when upgrading from a previous version of COM for OpenVMS.

D.1.1 Rebuild Existing COM for OpenVMS Applications

If your COM for OpenVMS applications include references to any of the following APIs, you must recompile the modules that include the references and relink the application:

- LoadLibraryA
- LoadLibraryW
- LoadLibraryExW
- LoadLibraryExA
- GetModuleFileNameA
- GetModuleFileNameW
- GetModuleHandleW
- GetProcAddress
- FreeLibrary

Some sample COM applications that shipped with COM Version 1.0 for OpenVMS include references to these APIs in the modules REGISTRY and CMPNT. If you built any samples, or if you built your own COM applications based on these samples, you should recompile and relink those applications.

D.1.2 Configuring the Windows NT Systems

For COM Version 1.0 for OpenVMS (unauthenticated COM) the COM for OpenVMS documentation instructed you to change specific values in your Windows NT registry to allow unauthenticated COM for OpenVMS to interoperate with Windows NT. COM Version 1.1-A for OpenVMS and COM Version 1.1-B for OpenVMS support authentication. As a result, you must set or reset the Windows NT Registry values we asked you to change for COM Version 1.0 for OpenVMS back to their default authenticated settings. To set the Windows NT Registry values, use the following procedure:

1. Start the Windows NT Registry editor.
2. Select the following registry key:

   HKEY_LOCAL_MACHINE\Software\Microsoft\Ole
Upgrading to COM Version 1.1-B for OpenVMS from COM Version 1.0 for OpenVMS

D.1 Upgrading from Earlier Versions of COM for OpenVMS

3. Delete the following value names and value data:

<table>
<thead>
<tr>
<th>Value name</th>
<th>Recommended COM V1.0 setting</th>
<th>Default (Authenticated) Value data (COM V1.1-B setting)</th>
<th>Registry type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActivationSecurity</td>
<td>N</td>
<td>Remove</td>
<td>REG_SZ</td>
</tr>
<tr>
<td>PersonalClasses</td>
<td>N</td>
<td>Remove</td>
<td>REG_SZ</td>
</tr>
</tbody>
</table>

4. Verify the Default Authentication Level and Default Impersonation Level and change if necessary. Use the following procedure:

   Note
   You must have Windows NT Administrator privileges to view and update these settings.

   a. From the Start menu, choose Run...
   b. In the Run dialog box, enter dcomcnfg.
      The system displays the Distributed COM Configuration Properties sheet.
   c. Click the Default Properties tab.
      • The Default Authentication Level list box should display Connect. If it does not, click the list box arrow and select Connect from the list.
      • The Default Impersonation Level list box should display Identity. If it does not, click the list box arrow and select Identity from the list.

5. You must reboot the Windows NT system for these changes to take effect.

D.1.3 Configuring the OpenVMS System

On OpenVMS systems, you must set or reset the specific OpenVMS Registry values. You can use the Windows NT Registry editor to edit the OpenVMS Registry, or you can use the REG$CP utility. To set the OpenVMS Registry values, use the following procedure:

1. Select the following OpenVMS Registry key:

   HKEY_LOCAL_MACHINE\Software\Microsoft\Ole

2. Delete the ActivationSecurity, PersonalClasses, LegacyAuthenticationLevel, and LegacyImpersonationLevel keys. Use the following commands to delete the keys:

   $ MCR REG$CP
   REG> LIST VALUE HKEY_LOCAL_MACHINE\Software\Microsoft\Ole ActivationSecurity
   REG> DELETE VALUE HKEY_LOCAL_MACHINE\Software\Microsoft\Ole ActivationSecurity
   REG> DELETE VALUE HKEY_LOCAL_MACHINE\Software\Microsoft\Ole PersonalClasses
   REG> DELETE VALUE HKEY_LOCAL_MACHINE\Software\Microsoft\Ole LegacyAuthenticationLevel
   REG> DELETE VALUE HKEY_LOCAL_MACHINE\Software\Microsoft\Ole LegacyImpersonationLevel
   REG> LIST VALUE HKEY_LOCAL_MACHINE\Software\Microsoft\Ole
   REG> EXIT
D.2 Previously Configured Applications on Windows NT

If you configured an application to run with COM Version 1.0 for OpenVMS (unauthenticated COM for OpenVMS) on Windows NT, you might want to reconfigure the Windows NT settings to take advantage of COM Version 1.1-B for OpenVMS (authenticated COM for OpenVMS).

Under COM Version 1.0 for OpenVMS after you registered a component, the COM for OpenVMS documentation instructed you to check the security properties on that component to ensure that an unauthenticated user can activate the image. Use the following procedure:

1. From the Windows NT Start menu, choose Run...
2. In the Run dialog box, enter dcomcnfg.
   The system displays the Distributed COM Configuration Properties sheet.
3. Select the object by name from the Applications list, then click the Properties... button.
   The system displays the property sheet for the selected object.
4. From the property sheet, click the Security tab.
   • For COM Version 1.0 for OpenVMS you had to set the access permissions (Registry value AccessPermission) so that user Everyone was allowed access (Allow access).
   For COM Version 1.1-B for OpenVMS, you can set custom access permissions (Registry value AccessPermission) to a specific user.
   Click Use custom access permissions, then click the Edit button to display the Registry Key Permissions box.
   • For COM Version 1.0 for OpenVMS you had to set the launch permissions (Registry value LaunchPermission) so that user Everyone was allowed to launch the application server (Allow launch).
   For COM Version 1.1-B for OpenVMS, you can set the custom launch permissions (Registry value LaunchPermission) to remove Everyone.
   Click Use custom access permissions, then click the Edit button to display the Registry Key Permissions box.
   • For COM Version 1.0 for OpenVMS you had to set the configuration permissions so that user Everyone was allowed at least Read access to the Registry values.
   For COM Version 1.1-B for OpenVMS, you can set the custom configuration permissions to remove Everyone.
   Click Use custom access permissions, then click the Edit button to display the Registry Key Permissions box.

Under COM Version 1.0 for OpenVMS after you set security properties, you had to set the identity of the account to run the application.
For COM Version 1.1-B for OpenVMS, you can set the identity of the account to option 1 or 2.
Click the Identity tab to display the user account selection. Select The interactive user option.
D.2 Previously Configured Applications on Windows NT

D.2.1 You Must Repopulate the OpenVMS Registry for COM Version 1.1-B for OpenVMS

For COM Version 1.1-B for OpenVMS, you must repopulate the OpenVMS Registry to include security settings. Use the DCOM$SETUP command procedure to display the OpenVMS COM Tools menu, and choose option 3.

D.2.2 Changing Application Security Settings in the OpenVMS Registry

COM Version 1.0 for OpenVMS, which shipped with OpenVMS 7.2, did not support NTLM security. As a result, the OpenVMS account through which you (or the system) registered the COM Version 1.0 for OpenVMS COM application was the owner for any OpenVMS Registry keys created as part of the application registration. For example, using COM Version 1.0 for OpenVMS, if you logged into the SYSTEM account and registered the SAMPLE1 application, all SAMPLE1's OpenVMS Registry keys are owned by SYSTEM.

COM Version 1.1-B for OpenVMS supports NTLM security. The system now uses the network account to control access to the OpenVMS Registry keys. As a result of this change, previous security settings might prevent a nonprivileged user from accessing an application's registry keys. This means that a nonprivileged user working on an existing application might not be able to unregister or reregister an application.

To prevent this registration lockout, you must change the permission of the application. You can change the permission from either the Windows NT system or the OpenVMS system. Use either of the following procedures:

- Changing the permission from a Windows NT system
  1. From a Windows NT system, start RegEdt32.
  2. From the Registry menu, choose Select Computer and connect to the OpenVMS system that contains the OpenVMS Registry.
  3. Select the key associated with the application you want to change.
  4. From the Security menu, choose Permissions... and grant the user Full Control.
  5. Repeat the last two steps for each registry key associated with the application. For a list of COM application-related registry keys, see Section D.2.2.1.

- Changing the permission from an OpenVMS system
  1. Log into a privileged OpenVMS account.
  2. Unregister the application. Use the DCOM$REGSVR32 utility. See Example 6–5.
  3. Delete all registry keys associated with the application. For a list of COM application-related registry keys, see Section D.2.2.1.
  4. Log into the nonprivileged user account.
  5. Register the application. Use the DCOM$REGSVR32 utility (see Example 6–4), or from the OpenVMS COM Tools menu, choose option 6 (see Section 6.2).
D.2.2.1 COM Application Registry Keys

A COM application can have several registry keys associated with it. You must be sure to change all keys associated with the application. An application usually registers the following keys:

- `HKEY_CLASSES_ROOT\CLSID\{guid}\` and subkeys
- `HKEY_CLASSES_ROOT\APPID\{guid}\`
- `HKEY_CLASSES_ROOT\APPID\filename`
- `HKEY_CLASSES_ROOT\TYPELIB\{typelib guid}\`
- `HKEY_CLASSES_ROOT\INTERFACES\{interface guid(s)\}\` and subkeys
- `HKEY_CLASSES_ROOT\name\` and subkeys
- `HKEY_CLASSES_ROOT\version independent name and subkeys`

Note: `HKEY_CLASSES_ROOT` is an alias for `HKEY_LOCAL_MACHINE\SOFTWARE\Classes`. If you connect to the OpenVMS Registry from Windows NT using Regedt32 and you want to edit the `HKEY_CLASSES_ROOT key`, edit the `HKEY_LOCAL_MACHINE\SOFTWARE\Classes` key.
Running COM Version 1.1-B for OpenVMS in an Unauthenticated Mode

COM Version 1.1-B for OpenVMS includes an option that allows you to run the software in an unauthenticated environment in which NTLM support is not utilized. If you enable this option, only OpenVMS security semantics are used to control COM applications’ access to resources. This is essentially the same behavior as in COM Version 1.0 for OpenVMS.

For a list of security differences between an unauthenticated implementation and an authenticated implementation of COM for OpenVMS, see Table 1–1.

Note

When you run COM for OpenVMS in unauthenticated mode, detached processes started by DCOM$RPCSS to run COM servers run in the context of the OpenVMS DCOM$GUEST account. These detached processes have the security attributes of the DCOM$GUEST account.

The following sections describes tasks you must complete in order to run COM for OpenVMS in an unauthenticated environment.

E.1 Installing COM V1.1-B for OpenVMS to Run in Unauthenticated Mode

If you are installing COM for OpenVMS for the first time, or if you are upgrading from an earlier version, perform the following steps:

• Follow the installation and upgrade procedures described in Chapter 4. Note: You can skip the steps relating to the installation, configuration, and startup of Advanced Server for OpenVMS.
• Follow the configuration procedures in Section E.2 to configure COM for OpenVMS in unauthenticated mode.

The ACME Server process is started automatically by RPC, but it is not required if you are in unauthenticated mode. To cause the ACME Server process to not start when the system reboots, edit the SYLOGICALS.COM file as follows:

$ DEFINE ACME$TO_BE_STARTER FALSE ! ACME Server
E.2 Configuring COM V1.1-B for OpenVMS to Run in Unauthenticated Mode

The following section describes how to configure COM Version 1.1-B for OpenVMS to run in an unauthenticated environment.

Note

Before you begin configuring COM for OpenVMS for unauthenticated mode, make a note of your current Windows NT system default values and application settings. This makes returning to authenticated mode easier. (See Section E.5 for information on how to convert from unauthenticated mode to authenticated mode.)

E.2.1 Define the DCOM$UNAUTHENTICATED Logical Systemwide

Define DCOM$UNAUTHENTICATED to be “Y” or “YES” systemwide. If this logical is undefined or defined as any other value, COM V1.1-B for OpenVMS will run in the usual authenticated mode utilizing NTLM security.

To cause COM for OpenVMS to start automatically in unauthenticated mode when the system boots, edit the SYLOGICALS.COM file and add the following line:

$ DEFINE/SYSTEM DCOM$UNAUTHENTICATED YES

E.2.2 Populate the OpenVMS Registry

Use option 3 in the DCOM$SETUP utility to populate the OpenVMS Registry. (See Section 6.2 for more information.)

Note

If you are upgrading from COM V1.1-A for OpenVMS, you do not need to populate the OpenVMS Registry.

E.2.3 Create the DCOM$GUEST Account

Create the OpenVMS DCOM$GUEST account using option 7 in the DCOM$SETUP utility. (See Section 6.2 for more information.)

E.2.4 Create the DCOM$RPCSS Account

Create the OpenVMS DCOM$RPCSS account using option 8 in the DCOM$SETUP utility. (See Section 6.2 for more information.)

E.3 Configuring Windows NT to Interoperate with Unauthenticated COM

For COM objects to interoperate correctly between unauthenticated COM V1.1-B for OpenVMS systems and Windows NT, perform the steps described in the following sections. This will configure the COM objects to run without security enabled on the Windows NT system.
E.3 Configuring Windows NT to Interoperate with Unauthenticated COM

E.3.1 Setting the Windows NT Systemwide Authentication Level
On Windows NT systems, set the systemwide authentication level using this procedure:
1. Run DCOMCNFG on the Windows NT system.
2. Select the Default Properties tab.
3. Set the Default Authentication Level to None.

E.3.2 Setting Windows NT Application Security Properties
After a COM application has been registered, check the security properties on that application to ensure that an unauthenticated user can activate the image.
To do this, perform the following steps:
1. Run DCOMCNFG on the Windows NT system.
2. Select the application by name.
3. Click the Properties button.
4. Click the Security tab.
Set the access permissions (Registry value AccessPermission) so that user Everyone is allowed access (Allow access).
Set the launch permissions (Registry value LaunchPermission) so that user Everyone is allowed access (Allow access).
Set the configuration permissions so that user Everyone is allowed at least Read access to the Registry values.

E.3.3 Setting the Windows NT Application Security Identity
After you set security permissions, you must set the identity of the account to run the application. To do this, click the Identity tab, and select The interactive user.

E.4 Expected Failures from CLIENTAUTH Sample Program
While you are running COM Version 1.1-B for OpenVMS in unauthenticated mode, the Cross-Domain Security example (CLIENTAUTH) does not work because it requires NTLM authentication to be enabled.

E.5 Converting from Unauthenticated Mode to Authenticated Mode
If you performed the steps in this appendix to run COM Version 1.1-B for OpenVMS in unauthenticated mode and you now want to return to authenticated mode, perform the following steps.
1. Log in to the SYSTEM account.
2. Stop the COM server. Use option 5 in the DCOM$SETUP utility. (See Section 6.2 for more information.)
3. Edit SYLOGICALS.COM with the following changes:
   • Undefine the DCOM$UNAUTHENTICATED logical by entering:
     $ DEFINE/SYSTEM DCOM$UNAUTHENTICATED NO
Running COM Version 1.1-B for OpenVMS in an Unauthenticated Mode

E.5 Converting from Unauthenticated Mode to Authenticated Mode

- Comment the following line, as shown:
  
  ```
  $! DEFINE ACME$TO_BE_STARTED FALSE ! ACME Server
  ```

4. Enter the following command:

  ```
  $ DEFINE/SYSTEM DCOM$UNAUTHENTICATED NO
  ```

5. Install, configure, and start Advanced Server for OpenVMS, if it is not already present.

6. Repopulate the OpenVMS Registry.
   To do this, use option 3 in the `DCOM$SETUP` utility. (See Section 6.2 for more information.)

7. Add the `DCOM$RPCSS` account to include the Advanced Server for OpenVMS account and hostmap. Use option 8 in the `DCOM$SETUP` utility. (See Section 6.2 for more information.)

8. Reset your Windows NT system default values and application settings to the values that were set before you followed the procedure in Section E.3.

9. Start the COM server. Use option 4 in the `DCOM$SETUP` utility. (See Section 6.2 for more information.)

10. Update or add network accounts. (See Section 5.1 for more information.)
Lists of Differences, APIs, and Interfaces

This appendix contains a list of implementation differences between COM for OpenVMS and Microsoft COM as well as a list of APIs and interfaces provided in this release of COM for OpenVMS.

F.1 Differences between COM for OpenVMS and Microsoft COM

The following sections list important implementation differences between COM for OpenVMS and Microsoft’s COM.

F.1.1 Service Control Manager (SCM)

OpenVMS does not provide an equivalent to the Windows NT Service Control Manager. As a result, applications that depend on Server services (such as stop, start, pause, and resume) rely on the OpenVMS features that provide similar functionality (if the features are available).

For example, you would use the OpenVMS site-specific startup and shutdown command procedures to implement automatic starting of services at system startup and automatic shutdown of services at system shutdown. Service APIs such as RegisterServiceCtrlHandler, ChangeServiceConfig, and so on, are not provided on OpenVMS.

F.1.2 Server Application Stack Size

In COM for OpenVMS, server application functions run in the context of server threads. As a result, server functions have a limited stack space of 48 KB. If you require additional space for local variables or structures, you should allocate dynamic memory for local variables or structures.

F.1.3 Use of the “char” Datatype

OpenVMS and Windows NT translate the IDL base data type “char” differently.

OpenVMS translates the data type as MIDL_CHAR, which is defined to be CHAR, and further defined to be “char.” The OpenVMS compiler by default takes this to be equivalent to “unsigned char;” in most cases they can be used interchangeably. The two are not the same—C++ treats them as different data types you specify them in class member definitions.

Windows NT translates the data type directly as “unsigned char.” This causes conflicts with Visual C++, which treats the “char” datatype as equivalent to “signed char.” As in OpenVMS, “char” is not the same as “signed char” in class member definitions.

There are two workarounds to this mismatch:

• Use the data type “CHAR” instead of “char” in the IDL file and all member definitions. This is the most portable solution; you can expect this to work on other systems (such as UNIX) as well.
Lists of Differences, APIs, and Interfaces

F.1 Differences between COM for OpenVMS and Microsoft COM

• Conditionally compile the method definitions so that OpenVMS sees the object methods defined as “char” and Windows NT sees the methods defined as “unsigned char.”

F.1.4 MIDL Compiler Version

The MIDL compiler supplied with COM for OpenVMS is based on Microsoft’s MIDL compiler V3.00.44.

F.1.4.1 The OpenVMS MIDL Compiler

The OpenVMS MIDL compiler is identical to the Microsoft Interface Definition Language (MIDL) compiler V3.00.44 except for the following:

1. The Microsoft MIDL implementation supports several optimization levels. The OpenVMS MIDL implementation supports only -Oicf. Do not use any other optimization level.

2. The /cpp_cmd and /cpp_opt switches are not fully functional in the OpenVMS MIDL implementation.

3. On a Windows NT system, Microsoft MIDL commands, switches, and qualifiers are case sensitive. The OpenVMS MIDL compiler is not case sensitive; all commands, switches, and qualifiers passed to the OpenVMS MIDL compiler are lowercase. As a result, the Microsoft MIDL switches /I and /i are equivalent on OpenVMS.

4. MIDL-generated files are platform specific.

   You must run MIDL on both platforms. The MIDL output files generated on one platform (OpenVMS or Windows NT) cannot be copied and used on the other platform.

5. MIDL -w switch

   The Microsoft MIDL compiler allows you to specify either -w or -warn to limit the level of warnings generated by the compiler. The OpenVMS MIDL compiler supports only the -w switch.

F.1.5 Using DCOM$CNFG to Change Application Configuration Permission

Use the Application Security Submenu options 5 and 6 to change the OpenVMS Registry key permissions of some keys associated with an application. Option 5 and 6 affect the security settings of the following keys:

\texttt{HKEY\_CLASSES\_ROOT\APPID\{guid\}}
\texttt{HKEY\_CLASSES\_ROOT\CLSID\{guid\} and subkeys}

On Windows NT systems, the security settings of the subkeys under
\texttt{HKEY\_CLASSES\_ROOT\CLSID\{guid\}} are changed only if the existing security settings match the original settings of \texttt{HKEY\_CLASSES\_ROOT\APPID\{guid\}}.

On OpenVMS systems, the settings of the subkeys are changed even if the existing settings do not match the original settings of \texttt{HKEY\_CLASSES\_ROOT\APPID\{guid\}}.

Options 5 and 6 do not change the settings of all keys associated with an application. For example, options 5 and 6 do not affect the following keys:

\texttt{HKEY\_CLASSES\_ROOT\APPID\filename}
\texttt{HKEY\_CLASSES\_ROOT\TYPELIB\{typelib guid\}}
\texttt{HKEY\_CLASSES\_ROOT\INTERFACES\{interface guid(s)\} and subkeys.}
\texttt{HKEY\_CLASSES\_ROOT\name and subkeys}
\texttt{HKEY\_CLASSES\_ROOT\version independent name and subkeys}
To change the security settings of these keys, use the following procedure:

1. From a Windows NT system, start RegEdt32.
2. From the Registry menu, choose Select Computer and connect to the OpenVMS system that contains the OpenVMS Registry.
3. Select the key associated with the application you want to change.
4. From the Security menu, choose Permissions... and grant the user Full Control.
5. Repeat the last two steps for each registry key associated with the application (see the list of keys described earlier in this section).

Note

HKEY_CLASSES_ROOT is an alias for HKEY_LOCAL_MACHINE\SOFTWARE\Classes. If you connect to the OpenVMS Registry from Windows NT using Regedt32 and you want to edit the HKEY_CLASSES_ROOT key, edit the HKEY_LOCAL_MACHINE\SOFTWARE\Classes key.

F.2 APIs

APIs that require security support are not supported in COM Version 1.0 for OpenVMS.

The APIs supported in this release are as follows:

BindMoniker
BstrFromVector
CLSIDFromProgID
CLSIDFromString
CoAddRefServerProcess
CoCopyProxy
CoCreateErrorInfo
CoCreateFreeThreadedMarshaler
CoCreateGuid
CoCreateInstance
CoCreateInstanceEx
CoDisconnectObject
CoDosDateTimeToFileTime
CoFileTimeNow
CoFileTimeToFileDosDateTime
CoFreeAllLibraries
CoFreeLibrary
CoFreeUnusedLibraries
CoGetCallContext
CoGetClassObject
CoGetCurrentProcess
CoGetErrorInfo
CoGetInstanceFromFile
CoGetInstanceFromIStorage
CoGetInterfaceAndReleaseStream
CoGetMalloc
CoGetMarshalSizeMax
CoGetPSClsid
CoGetStandardMarshal
CoGetTreatAsClass
Lists of Differences, APIs, and Interfaces
F.2 APIs

CoImpersonateClient
CoInitialize
CoInitializeEx
CoInitializeSecurity
CoIsHandlerConnected
CoLoadLibrary
CoLockObjectExternal
CoMarshalInterface
CoQueryAuthenticationServices
CoQueryClientBlanket
CoQueryProxyBlanket
CoRegisterChannelHook
CoRegisterClassObject
CoRegisterMallocSpy
CoRegisterMessageFilter
CoRegisterPSClsid
CoReleaseMarshalData
CoReleaseServerProcess
CoResumeClassObjects
CoRevertToSelf
CoRevokeClassObject
CoRevokeMallocSpy
CoSetErrorInfo
CoSetProxyBlanket
CoSuspendClassObjects
CoTaskMemAlloc
CoTaskMemFree
CoTaskMemRealloc
CoTreatAsClass
CoUninitialize
CoUnmarshalInterface
CreateAntiMoniker
CreateBindCtx
CreateClassMoniker
CreateDataAdviseHolder
CreateDispTypeInfo
CreateErrorInfo
CreateGenericComposite
CreateILockBytesOnHGlobal
CreateItemMoniker
CreatePointerMoniker
CreateStdDispatch
CreateStreamOnHGlobal
CreateTypeLib
DispGetIDsofNames
DispGetParam
DispInvoke
DllCanUnloadNow
DllGetClassObject
DllGetClassObject
DllMain
DllRegisterServer
DllUnregisterServer
DosDateTimeToVariantTime
FreePropVariantArray
GetActiveObject
GetAltMonthNames
GetClassFile
GetConvertStg
GetErrorInfo
GetHGlobalFromILockBytes
GetHGlobalFromStream
GetRunningObjectTable
IIDFromString
IsEqualCLSID
Lists of Differences, APIs, and Interfaces

F.2 APIs

IsEqualGUID
IsEqualIID
IsValidIID
IsValidInterface
IsValidPtrIn
IsValidPtrOut
IHashValOfName
IHashValOfNameSys
LoadRegTypeLib
LoadTypeLibEx
 MkParseDisplayName
 MonikerCommonPrefixWith
 MonikerRelativePathTo
 ProgIDFromCLSID
 PropStgNameToFmtId
 PropVariantClear
 PropVariantCopy

Discount Coupons for COM Books

By special arrangement with the publishers, Compaq is able to provide COM for OpenVMS developers with the following discount coupons for some of the third-party COM books mentioned in this manual. Please follow the instructions on the coupon when ordering books.

COUPON

Essential COM
by Don Box, Addison-Wesley Object Technology Series

Essential COM helps developers go beyond simplistic applications of COM and become truly effective COM programmers. You will find comprehensive coverage of core concepts of Distributed COM (interfaces, classes, apartments, and applications), including detailed descriptions of COM theory, the C++ language mapping, COM IDL (Interface Definition Language), the remoting architecture, IUnknown, monikers, threads, marshalers, security, and more. Written by the premier authority on the COM architecture, this book offers a thorough explanation of COM's basic vocabulary, provides a complete Distributed COM application to illustrate programming techniques, and includes the author's test library of COM utility code. By showing the why of COM, not just the how, Don Box enables you to apply the model creatively and effectively to everyday programming problems.

As a Compaq customer, this book is offered to you by Addison Wesley Longman at a 20% discount

Effective COM
50 Ways to Improve your COM and MTS-based Applications
by Don Box, Keith Brown, Tim Ewald, and Chris Sells, Addison-Wesley Object Technology Series

Written by best-selling author Don Box, along with other instructors from DevelopMentor, Effective COM offers fifty concrete guidelines for COM derived from the communal wisdom formed over the past five years of COM-based development. This book is targeted at developers who are living and breathing COM, humbled by its complexity and challenged by the breadth of distributed object computing. Although the book is written for developers who work in C++, many of the topics (e.g., interface design and security) are accessible by developers who work in Visual Basic®, Java®, or Object Pascal. The authors, four COM experts, provide insight on complex subjects such as the difference between pure C++ development and COM-based C++ development, COM interface design, concurrency and apartments, and security. ISBN: 0-201-37968-6, Paperback, 240 pages. Copyright © 1999.

As a Compaq customer,

DCOM Explained
by Rosemary Rock-Evans

DCOM Explained helps describes what services DCOM provides, both development and runtime. Thus the aim of the book is not to teach how to program using DCOM, but to explain what DCOM does so readers will become better able to use it more effectively, understand the options available when using DCOM, and understand the types of applications that can be built by using DCOM.

As a Compaq customer,
this book is offered to you by Digital Press at a 20% discount
class (registry class)  
Registry element attribute that allows you to store additional descriptive information with a registry key or subkey.

encapsulation  
The process of updating or extending the life of existing application code by leaving most of the code and its functionality intact, while including new or updated code (usually in a different programming language) at key entry points.  
For example, you might add a Windows graphical interface to a character-cell application by writing some Visual Basic code that collects information from a Windows client, then formats and submits the data to the existing character cell application as if the data had come from the character cell interface.

hive  
A discrete set of keys, subkeys, and value entries contained in the registry.

in-process server  
An application that is located on the same system as the requesting client. On Windows NT systems, in-process servers are usually implemented as DLLs. On OpenVMS systems, in-process servers are usually implemented as shareable images.

key (registry key)  
Registry element that contains information specific to the computer, system, or user.

out-of-process server  
An application that is located on a different system than the requesting client. On Windows NT systems, out-of-process servers are usually implemented as .EXE files.

registry  
A hierarchical database consisting of one or more files that stores configuration information about system hardware and software.

subkey (registry subkey)  
Registry element that is a child of a registry key. A registry key can have zero or more subkeys.

value (registry value)  
Registry element that is the entry or value for a registry key or subkey.
Glossary

wrapper
See encapsulation.
